## INTRODUCTION

The 8051 is the original member of the MCS®-51 family, and is the core for all MCS-51 devices. The features of the 8051 core are:

- 8-bit CPU optimized for control applications
- Extensive Boolean processing (single-bit logic) capabilities
- 64K Program Memory address space
- 64K Data Memory address space
- 4K bytes of on-chip Program Memory
- 128 bytes of on-chip Data RAM
- 32 bidirectional and individually addressable I/O lines
- Two 16-bit timer/counters
- Full duplex UART
- 6-source/5-vector interrupt structure with two priority levels
- On-chip clock oscillator

The basic architectural structure of this 8051 core is shown in Figure 1.

**Figure 1. Block Diagram of the 8051 Core**

## CHMOS Devices

Functionally, the CHMOS devices (designated with "C" in the middle of the device name) are all fully compatible with the 8051, but being CMOS, draw less current than an HMOS counterpart. To further exploit the power savings available in CMOS circuitry, two reduced power modes are added:

- Software-invoked Idle Mode, during which the CPU is turned off while the RAM and other on-chip peripherals continue operating. In this mode, current draw is reduced to about 15% of the current drawn when the device is fully active.
- Software-invoked Power Down Mode, during which all on-chip activities are suspended. The on-chip RAM continues to hold its data. In this mode the device typically draws less than 10  $\mu$ A.

Although the 80C51BH is functionally compatible with its HMOS counterpart, specific differences between the two types of devices must be considered in the design of an application circuit if one wishes to ensure complete interchangeability between the HMOS and CHMOS devices. These considerations are discussed in the Application Note AP-252, "Designing with the 80C51BH".

For more information on the individual devices and features listed in Table 1, refer to the Hardware Descriptions and Data Sheets of the specific device.

## MEMORY ORGANIZATION IN MCS®-51 DEVICES

### Logical Separation of Program and Data Memory

All MCS-51 devices have separate address spaces for Program and Data Memory, as shown in Figure 2. The logical separation of Program and Data Memory allows the Data Memory to be accessed by 8-bit addresses, which can be more quickly stored and manipulated by an 8-bit CPU. Nevertheless, 16-bit Data Memory addresses can also be generated through the DPTR register.

Program Memory can only be read, not written to. There can be up to 64K bytes of Program Memory. In the ROM and EPROM versions of these devices the lowest 4K, 8K or 16K bytes of Program Memory are provided on-chip. Refer to Table 1 for the amount of on-chip ROM (or EPROM) on each device. In the ROMless versions all Program Memory is external. The read strobe for external Program Memory is the signal PSEN (Program Store Enable).

Data Memory occupies a separate address space from Program Memory. Up to 64K bytes of external RAM can be addressed in the external Data Memory space. The CPU generates read and write signals,  $\overline{RD}$  and  $\overline{WR}$ , as needed during external Data Memory accesses.

External Program Memory and external Data Memory may be combined if desired by applying the  $\overline{RD}$  and  $\overline{PSEN}$  signals to the inputs of an AND gate and using the output of the gate as the read strobe to the external Program/Data memory.

## Program Memory

Figure 3 shows a map of the lower part of the Program Memory. After reset, the CPU begins execution from location 0000H.

As shown in Figure 3, each interrupt is assigned a fixed location in Program Memory. The interrupt causes the CPU to jump to that location, where it commences execution of the service routine. External Interrupt 0, for example, is assigned to location 0003H. If External Interrupt 0 is going to be used, its service routine must begin at location 0003H. If the interrupt is not going to be used, its service location is available as general purpose Program Memory.

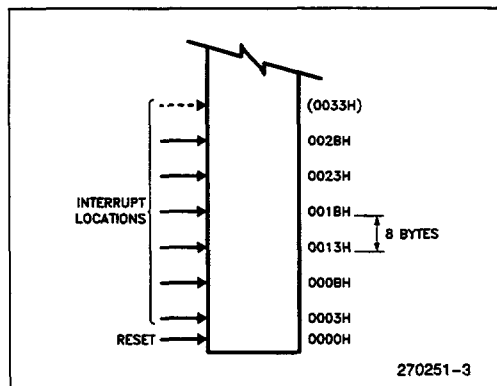

Figure 3. MCS®-51 Program Memory

The interrupt service locations are spaced at 8-byte intervals: 0003H for External Interrupt 0, 000BH for Timer 0, 0013H for External Interrupt 1, 001BH for Timer 1, etc. If an interrupt service routine is short enough (as is often the case in control applications), it can reside entirely within that 8-byte interval. Longer service routines can use a jump instruction to skip over subsequent interrupt locations, if other interrupts are in use.

The lowest 4K (or 8K or 16K) bytes of Program Memory can be either in the on-chip ROM or in an external ROM. This selection is made by strapping the  $\overline{EA}$  (External Access) pin to either  $V_{CC}$  or  $V_{SS}$ .

In the 4K byte ROM devices, if the  $\overline{EA}$  pin is strapped to  $V_{CC}$ , then program fetches to addresses 0000H through 0FFFH are directed to the internal ROM. Program fetches to addresses 1000H through FFFFH are directed to external ROM.

In the 8K byte ROM devices,  $\overline{EA} = V_{CC}$  selects addresses 0000H through 1FFFH to be internal, and addresses 2000H through FFFFH to be external.

In the 16K byte ROM devices,  $\overline{EA} = V_{CC}$  selects addresses 0000H through 3FFFH to be internal, and addresses 4000H through FFFFH to be external.

If the  $\overline{EA}$  pin is strapped to  $V_{SS}$ , then all program fetches are directed to external ROM. The ROMless parts must have this pin externally strapped to  $V_{SS}$  to enable them to execute properly.

The read strobe to external ROM,  $\overline{PSEN}$ , is used for all external program fetches.  $\overline{PSEN}$  is not activated for internal program fetches.

Figure 4. Executing from External Program Memory

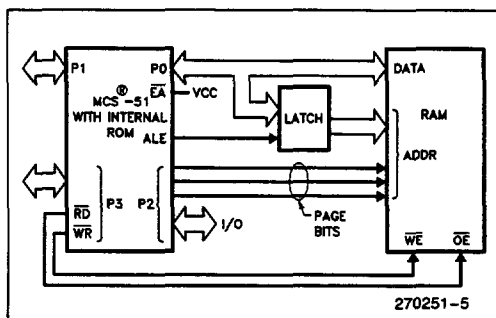

The hardware configuration for external program execution is shown in Figure 4. Note that 16 I/O lines (Ports 0 and 2) are dedicated to bus functions during external Program Memory fetches. Port 0 (P0 in Figure 4) serves as a multiplexed address/data bus. It emits the low byte of the Program Counter (PCL) as an address, and then goes into a float state awaiting the arrival of the code byte from the Program Memory. During the time that the low byte of the Program Counter is valid on P0, the signal ALE (Address Latch Enable) clocks this byte into an address latch. Meanwhile, Port 2 (P2 in Figure 4) emits the high byte of the Program Counter (PCH). Then  $\overline{PSEN}$  strobes the EPROM and the code byte is read into the microcontroller.

Program Memory addresses are always 16 bits wide, even though the actual amount of Program Memory used may be less than 64K bytes. External program execution sacrifices two of the 8-bit ports, P0 and P2, to the function of addressing the Program Memory.

## Data Memory

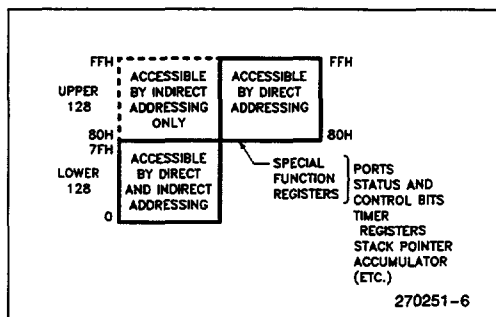

The right half of Figure 2 shows the internal and external Data Memory spaces available to the MCS-51 user.

Figure 5 shows a hardware configuration for accessing up to 2K bytes of external RAM. The CPU in this case is executing from internal ROM. Port 0 serves as a multiplexed address/data bus to the RAM, and 3 lines of Port 2 are being used to page the RAM. The CPU generates RD and WR signals as needed during external RAM accesses.

**Figure 5. Accessing External Data Memory.**  
If the Program Memory is Internal, the Other Bits of P2 are Available as I/O.

There can be up to 64K bytes of external Data Memory. External Data Memory addresses can be either 1 or 2 bytes wide. One-byte addresses are often used in conjunction with one or more other I/O lines to page the RAM, as shown in Figure 5. Two-byte addresses can also be used, in which case the high address byte is emitted at Port 2.

**Figure 6. Internal Data Memory**

Internal Data Memory is mapped in Figure 6. The memory space is shown divided into three blocks, which are generally referred to as the Lower 128, the Upper 128, and SFR space.

Internal Data Memory addresses are always one byte wide, which implies an address space of only 256 bytes. However, the addressing modes for internal RAM can in fact accommodate 384 bytes, using a simple trick. Direct addresses higher than 7FH access one memory space, and indirect addresses higher than 7FH access a different memory space. Thus Figure 6 shows the Upper 128 and SFR space occupying the same block of addresses, 80H through FFH, although they are physically separate entities.

**Figure 7. The Lower 128 Bytes of Internal RAM**

The Lower 128 bytes of RAM are present in all MCS-51 devices as mapped in Figure 7. The lowest 32 bytes are grouped into 4 banks of 8 registers. Program instructions call out these registers as R0 through R7. Two bits in the Program Status Word (PSW) select which register bank is in use. This allows more efficient use of code space, since register instructions are shorter than instructions that use direct addressing.

**Figure 8. The Upper 128 Bytes of Internal RAM**

Figure 10. PSW (Program Status Word) Register in MCS®-51 Devices

The next 16 bytes above the register banks form a block of bit-addressable memory space. The MCS-51 instruction set includes a wide selection of single-bit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00H through 7FH.

All of the bytes in the Lower 128 can be accessed by either direct or indirect addressing. The Upper 128 (Figure 8) can only be accessed by indirect addressing. The Upper 128 bytes of RAM are not implemented in the 8051, but are in the devices with 256 bytes of RAM. (See Table 1).

Figure 9 gives a brief look at the Special Function Register (SFR) space. SFRs include the Port latches, timers, peripheral controls, etc. These registers can only be accessed by direct addressing. In general, all MCS-51 microcontrollers have the same SFRs as the 8051, and at the same addresses in SFR space. However, enhancements to the 8051 have additional SFRs that are not present in the 8051, nor perhaps in other proliferations of the family.

Figure 9. SFR Space

Sixteen addresses in SFR space are both byte- and bit-addressable. The bit-addressable SFRs are those whose address ends in 00B. The bit addresses in this area are 80H through FFH.

## THE MCS®-51 INSTRUCTION SET

All members of the MCS-51 family execute the same instruction set. The MCS-51 instruction set is optimized for 8-bit control applications. It provides a variety of fast addressing modes for accessing the internal RAM to facilitate byte operations on small data structures. The instruction set provides extensive support for one-bit variables as a separate data type, allowing direct bit manipulation in control and logic systems that require Boolean processing.

An overview of the MCS-51 instruction set is presented below, with a brief description of how certain instructions might be used. References to "the assembler" in this discussion are to Intel's MCS-51 Macro Assembler, ASM51. More detailed information on the instruction set can be found in the MCS-51 Macro Assembler User's Guide (Order No. 9800937 for ISIS Systems, Order No. 122752 for DOS Systems).

## Program Status Word

The Program Status Word (PSW) contains several status bits that reflect the current state of the CPU. The PSW, shown in Figure 10, resides in SFR space. It contains the Carry bit, the Auxiliary Carry (for BCD operations), the two register bank select bits, the Overflow flag, a Parity bit, and two user-definable status flags.

The Carry bit, other than serving the functions of a Carry bit in arithmetic operations, also serves as the "Accumulator" for a number of Boolean operations.

The bits RS0 and RS1 are used to select one of the four register banks shown in Figure 7. A number of instructions refer to these RAM locations as R0 through R7. The selection of which of the four banks is being referred to is made on the basis of the bits RS0 and RS1 at execution time.

The Parity bit reflects the number of 1s in the Accumulator:  $P = 1$  if the Accumulator contains an odd number of 1s, and  $P = 0$  if the Accumulator contains an even number of 1s. Thus the number of 1s in the Accumulator plus  $P$  is always even.

Two bits in the PSW are uncommitted and may be used as general purpose status flags.

## Addressing Modes

The addressing modes in the MCS-51 instruction set are as follows:

### DIRECT ADDRESSING

In direct addressing the operand is specified by an 8-bit address field in the instruction. Only internal Data RAM and SFRs can be directly addressed.

### INDIRECT ADDRESSING

In indirect addressing the instruction specifies a register which contains the address of the operand. Both internal and external RAM can be indirectly addressed.

The address register for 8-bit addresses can be R0 or R1 of the selected register bank, or the Stack Pointer. The address register for 16-bit addresses can only be the 16-bit "data pointer" register, DPTR.

### REGISTER INSTRUCTIONS

The register banks, containing registers R0 through R7, can be accessed by certain instructions which carry a 3-bit register specification within the opcode of the instruction. Instructions that access the registers this way are code efficient, since this mode eliminates an address byte. When the instruction is executed, one of the eight registers in the selected bank is accessed. One of four banks is selected at execution time by the two bank select bits in the PSW.

### REGISTER-SPECIFIC INSTRUCTIONS

Some instructions are specific to a certain register. For example, some instructions always operate on the Accumulator, or Data Pointer, etc., so no address byte is needed to point to it. The opcode itself does that. Instructions that refer to the Accumulator as A assemble as accumulator-specific opcodes.

### IMMEDIATE CONSTANTS

The value of a constant can follow the opcode in Program Memory. For example,

```
MOV A, #100
```

loads the Accumulator with the decimal number 100. The same number could be specified in hex digits as 64H.

### INDEXED ADDRESSING

Only Program Memory can be accessed with indexed addressing, and it can only be read. This addressing mode is intended for reading look-up tables in Program Memory. A 16-bit base register (either DPTR or the Program Counter) points to the base of the table, and the Accumulator is set up with the table entry number. The address of the table entry in Program Memory is formed by adding the Accumulator data to the base pointer.

Another type of indexed addressing is used in the "case jump" instruction. In this case the destination address of a jump instruction is computed as the sum of the base pointer and the Accumulator data.

## Arithmetic Instructions

The menu of arithmetic instructions is listed in Table 2. The table indicates the addressing modes that can be used with each instruction to access the <byte> operand. For example, the ADD A, <byte> instruction can be written as:

```
ADD A, 7FH    (direct addressing)
ADD A, @R0    (indirect addressing)
ADD A, R7     (register addressing)
ADD A, #127   (immediate constant)
```

The execution times listed in Table 2 assume a 12 MHz clock frequency. All of the arithmetic instructions execute in 1  $\mu$ s except the INC DPTR instruction, which takes 2  $\mu$ s, and the Multiply and Divide instructions, which take 4  $\mu$ s.

Note that any byte in the internal Data Memory space can be incremented or decremented without going through the Accumulator.

One of the INC instructions operates on the 16-bit Data Pointer. The Data Pointer is used to generate 16-bit addresses for external memory, so being able to increment it in one 16-bit operation is a useful feature.

The MUL AB instruction multiplies the Accumulator by the data in the B register and puts the 16-bit product into the concatenated B and Accumulator registers.

Table 2. A List of the MCS®-51 Arithmetic Instructions

Mnemonic	Operation	Addressing Modes				Execution Time (μs)
		Dir	Ind	Reg	Imm	
ADD A,<byte>	A = A + <byte>	X	X	X	X	1
ADDC A,<byte>	A = A + <byte> + C	X	X	X	X	1
SUBB A,<byte>	A = A - <byte> - C	X	X	X	X	1
INC A	A = A + 1	Accumulator only				1
INC <byte>	<byte> = <byte> + 1	X	X	X		1
INC DPTR	DPTR = DPTR + 1	Data Pointer only				2
DEC A	A = A - 1	Accumulator only				1
DEC <byte>	<byte> = <byte> - 1	X	X	X		1
MUL AB	B:A = B x A	ACC and B only				4
DIV AB	A = Int [A/B] B = Mod [A/B]	ACC and B only				4
DA A	Decimal Adjust	Accumulator only				1

The DIV AB instruction divides the Accumulator by the data in the B register and leaves the 8-bit quotient in the Accumulator, and the 8-bit remainder in the B register.

Oddly enough, DIV AB finds less use in arithmetic “divide” routines than in radix conversions and programmable shift operations. An example of the use of DIV AB in a radix conversion will be given later. In shift operations, dividing a number by 2<sup>n</sup> shifts its n bits to the right. Using DIV AB to perform the division

completes the shift in 4 μs and leaves the B register holding the bits that were shifted out.

The DA A instruction is for BCD arithmetic operations. In BCD arithmetic, ADD and ADDC instructions should always be followed by a DA A operation, to ensure that the result is also in BCD. Note that DA A will not convert a binary number to BCD. The DA A operation produces a meaningful result only as the second step in the addition of two BCD bytes.

Table 3. A List of the MCS®-51 Logical Instructions

Mnemonic	Operation	Addressing Modes				Execution Time (μs)
		Dir	Ind	Reg	Imm	
ANL A,<byte>	A = A .AND. <byte>	X	X	X	X	1
ANL <byte>,A	<byte> = <byte> .AND. A	X				1
ANL <byte>,#data	<byte> = <byte> .AND. #data	X				2
ORL A,<byte>	A = A .OR. <byte>	X	X	X	X	1
ORL <byte>,A	<byte> = <byte> .OR. A	X				1
ORL <byte>,#data	<byte> = <byte> .OR. #data	X				2
XRL A,<byte>	A = A .XOR. <byte>	X	X	X	X	1
XRL <byte>,A	<byte> = <byte> .XOR. A	X				1
XRL <byte>,#data	<byte> = <byte> .XOR. #data	X				2
CRL A	A = 00H	Accumulator only				1
CPL A	A = .NOT. A	Accumulator only				1
RL A	Rotate ACC Left 1 bit	Accumulator only				1
RLC A	Rotate Left through Carry	Accumulator only				1
RR A	Rotate ACC Right 1 bit	Accumulator only				1
RRC A	Rotate Right through Carry	Accumulator only				1
SWAP A	Swap Nibbles in A	Accumulator only				1

## Logical Instructions

Table 3 shows the list of MCS-51 logical instructions. The instructions that perform Boolean operations (AND, OR, Exclusive OR, NOT) on bytes perform the operation on a bit-by-bit basis. That is, if the Accumulator contains 00110101B and <byte> contains 01010011B, then

```
ANL    A,<byte>
```

will leave the Accumulator holding 00010001B.

The addressing modes that can be used to access the <byte> operand are listed in Table 3. Thus, the ANL A, <byte> instruction may take any of the forms

```
ANL    A,7FH      (direct addressing)
ANL    A,@R1      (indirect addressing)
ANL    A,R6        (register addressing)
ANL    A,#53H     (immediate constant)
```

All of the logical instructions that are Accumulator-specific execute in 1 $\mu$ s (using a 12 MHz clock). The others take 2  $\mu$ s.

Note that Boolean operations can be performed on any byte in the lower 128 internal Data Memory space or the SFR space using direct addressing, without having to use the Accumulator. The XRL <byte>, #data instruction, for example, offers a quick and easy way to invert port bits, as in

```
XRL    P1,#0FFH
```

If the operation is in response to an interrupt, not using the Accumulator saves the time and effort to stack it in the service routine.

The Rotate instructions (RL A, RLC A, etc.) shift the Accumulator 1 bit to the left or right. For a left rotation, the MSB rolls into the LSB position. For a right rotation, the LSB rolls into the MSB position.

The SWAP A instruction interchanges the high and low nibbles within the Accumulator. This is a useful operation in BCD manipulations. For example, if the Accumulator contains a binary number which is known to be less than 100, it can be quickly converted to BCD by the following code:

```
MOV    B,#10
DIV    AB
SWAP   A
ADD    A,B
```

Dividing the number by 10 leaves the tens digit in the low nibble of the Accumulator, and the ones digit in the B register. The SWAP and ADD instructions move the tens digit to the high nibble of the Accumulator, and the ones digit to the low nibble.

## Data Transfers

### INTERNAL RAM

Table 4 shows the menu of instructions that are available for moving data around within the internal memory spaces, and the addressing modes that can be used with each one. With a 12 MHz clock, all of these instructions execute in either 1 or 2  $\mu$ s.

The MOV <dest>, <src> instruction allows data to be transferred between any two internal RAM or SFR locations without going through the Accumulator. Remember the Upper 128 bytes of data RAM can be accessed only by indirect addressing, and SFR space only by direct addressing.

Note that in all MCS-51 devices, the stack resides in on-chip RAM, and grows upwards. The PUSH instruction first increments the Stack Pointer (SP), then copies the byte into the stack. PUSH and POP use only direct addressing to identify the byte being saved or restored,

**Table 4. A List of the MCS®-51 Data Transfer Instructions that Access Internal Data Memory Space**

Mnemonic	Operation	Addressing Modes				Execution Time ( $\mu$ s)
		Dir	Ind	Reg	Imm	
MOV A,<src>	A = <src>	X	X	X	X	1
MOV <dest>,A	<dest> = A	X	X	X		1
MOV <dest>,<src>	<dest> = <src>	X	X	X	X	2
MOV DPTR,#data16	DPTR = 16-bit immediate constant.				X	2
PUSH <src>	INC SP : MOV "@SP",<src>	X				2
POP <dest>	MOV <dest>,"@SP": DEC SP	X				2
XCH A,<byte>	ACC and <byte> exchange data	X	X	X		1
XCHD A,@Ri	ACC and @Ri exchange low nibbles		X			1

but the stack itself is accessed by indirect addressing using the SP register. This means the stack can go into the Upper 128, if they are implemented, but not into SFR space.

In devices that do not implement the Upper 128, if the SP points to the Upper 128, PUSHed bytes are lost, and POPped bytes are indeterminate.

The Data Transfer instructions include a 16-bit MOV that can be used to initialize the Data Pointer (DPTR) for look-up tables in Program Memory, or for 16-bit external Data Memory accesses.

The XCH A, <byte> instruction causes the Accumulator and addressed byte to exchange data. The XCHD A,@Ri instruction is similar, but only the low nibbles are involved in the exchange.

To see how XCH and XCHD can be used to facilitate data manipulations, consider first the problem of shifting an 8-digit BCD number two digits to the right. Figure 11 shows how this can be done using direct MOVs, and for comparison how it can be done using XCH instructions. To aid in understanding how the code works, the contents of the registers that are holding the BCD number and the content of the Accumulator are shown alongside each instruction to indicate their status after the instruction has been executed.

		2A	2B	2C	2D	2E	ACC
MOV	A,2EH	00	12	34	56	78	78
MOV	2EH,2DH	00	12	34	56	56	78
MOV	2DH,2CH	00	12	34	34	56	78
MOV	2CH,2BH	00	12	12	34	56	78
MOV	2BH,#0	00	00	12	34	56	78

(a) Using direct MOVs: 14 bytes, 9  $\mu$ s

		2A	2B	2C	2D	2E	ACC
CLR	A	00	12	34	56	78	00
XCH	A,2BH	00	00	34	56	78	12
XCH	A,2CH	00	00	12	56	78	34
XCH	A,2DH	00	00	12	34	78	56
XCH	A,2EH	00	00	12	34	56	78

(b) Using XCHs: 9 bytes, 5  $\mu$ s

**Figure 11. Shifting a BCD Number Two Digits to the Right**

After the routine has been executed, the Accumulator contains the two digits that were shifted out on the right. Doing the routine with direct MOVs uses 14 code bytes and 9  $\mu$ s of execution time (assuming a 12 MHz clock). The same operation with XCHs uses less code and executes almost twice as fast.

To right-shift by an odd number of digits, a one-digit shift must be executed. Figure 12 shows a sample of code that will right-shift a BCD number one digit, using the XCHD instruction. Again, the contents of the registers holding the number and of the Accumulator are shown alongside each instruction.

		2A	2B	2C	2D	2E	ACC
MOV	R1,#2EH	00	12	34	56	78	XX
MOV	R0,#2DH	00	12	34	56	78	XX

loop for R1 = 2EH:

LOOP:	MOV	A,@R1	00	12	34	56	78	78
	XCHD	A,@R0	00	12	34	58	78	76
	SWAP	A	00	12	34	58	78	67
	MOV	@R1,A	00	12	34	58	67	67
	DEC	R1	00	12	34	58	67	67
	DEC	R0	00	12	34	58	67	67
	CJNE	R1,#2AH,LOOP						

loop for R1 = 2DH:

		00	12	38	45	67	45
--	--	----	----	----	----	----	----

loop for R1 = 2CH:

		00	18	23	45	67	23
--	--	----	----	----	----	----	----

loop for R1 = 2BH:

		08	01	23	45	67	01
--	--	----	----	----	----	----	----

CLR	A	08	01	23	45	67	00
XCH	A,2AH	00	01	23	45	67	08

**Figure 12. Shifting a BCD Number One Digit to the Right**

First, pointers R1 and R0 are set up to point to the two bytes containing the last four BCD digits. Then a loop is executed which leaves the last byte, location 2EH, holding the last two digits of the shifted number. The pointers are decremented, and the loop is repeated for location 2DH. The CJNE instruction (Compare and Jump if Not Equal) is a loop control that will be described later.

The loop is executed from LOOP to CJNE for R1 = 2EH, 2DH, 2CH and 2BH. At that point the digit that was originally shifted out on the right has propagated to location 2AH. Since that location should be left with 0s, the lost digit is moved to the Accumulator.

## EXTERNAL RAM

Table 5 shows a list of the Data Transfer instructions that access external Data Memory. Only indirect addressing can be used. The choice is whether to use a one-byte address, @Ri, where Ri can be either R0 or R1 of the selected register bank, or a two-byte address, @DPTR. The disadvantage to using 16-bit addresses is if only a few K bytes of external RAM are involved is that 16-bit addresses use all 8 bits of Port 2 as address bus. On the other hand, 8-bit addresses allow one to address a few K bytes of RAM, as shown in Figure 5, without having to sacrifice all of Port 2.

All of these instructions execute in 2  $\mu$ s, with a 12 MHz clock.

**Table 5. A List of the MCS®-51 Data Transfer Instructions that Access External Data Memory Space**

Address Width	Mnemonic	Operation	Execution Time ( $\mu$ s)
8 bits	MOVX A,@Ri	Read external RAM @Ri	2
8 bits	MOVX @Ri,A	Write external RAM @Ri	2
16 bits	MOVX A,@DPTR	Read external RAM @DPTR	2
16 bits	MOVX @DPTR,A	Write external RAM @DPTR	2

Note that in all external Data RAM accesses, the Accumulator is always either the destination or source of the data.

The read and write strobes to external RAM are activated only during the execution of a MOVX instruction. Normally these signals are inactive, and in fact if they're not going to be used at all, their pins are available as extra I/O lines. More about that later.

## LOOKUP TABLES

Table 6 shows the two instructions that are available for reading lookup tables in Program Memory. Since these instructions access only Program Memory, the lookup tables can only be read, not updated. The mnemonic is MOVC for "move constant".

If the table access is to external Program Memory, then the read strobe is PSEN.

**Table 6. The MCS®-51 Lookup Table Read Instructions**

Mnemonic	Operation	Execution Time ( $\mu$ s)
MOVC A,@A+DPTR	Read Pgm Memory at (A+DPTR)	2
MOVC A,@A+PC	Read Pgm Memory at (A+PC)	2

The first MOVC instruction in Table 6 can accommodate a table of up to 256 entries, numbered 0 through 255. The number of the desired entry is loaded into the Accumulator, and the Data Pointer is set up to point to beginning of the table. Then

```
MOVC  A,@A+DPTR
```

copies the desired table entry into the Accumulator.

The other MOVC instruction works the same way, except the Program Counter (PC) is used as the table base, and the table is accessed through a subroutine. First the number of the desired entry is loaded into the Accumulator, and the subroutine is called:

```
MOV  A,ENTRY__NUMBER
CALL TABLE
```

The subroutine "TABLE" would look like this:

```
TABLE: MOVC  A,@A+PC
      RET
```

The table itself immediately follows the RET (return) instruction in Program Memory. This type of table can have up to 255 entries, numbered 1 through 255. Number 0 can not be used, because at the time the MOVC instruction is executed, the PC contains the address of the RET instruction. An entry numbered 0 would be the RET opcode itself.

## Boolean Instructions

MCS-51 devices contain a complete Boolean (single-bit) processor. The internal RAM contains 128 addressable bits, and the SFR space can support up to 128 other addressable bits. All of the port lines are bit-addressable, and each one can be treated as a separate single-bit port. The instructions that access these bits are not just conditional branches, but a complete menu of move, set, clear, complement, OR, and AND instructions. These kinds of bit operations are not easily obtained in other architectures with any amount of byte-oriented software.

**Table 7. A List of the MCS®-51 Boolean Instructions**

Mnemonic	Operation	Execution Time (μs)
ANL C,bit	C = C.AND. bit	2
ANL C,/bit	C = C.AND. .NOT. bit	2
ORL C,bit	C = C.OR. bit	2
ORL C,/bit	C = C.OR. .NOT. bit	2
MOV C,bit	C = bit	1
MOV bit,C	bit = C	2
CLR C	C = 0	1
CLR bit	bit = 0	1
SETB C	C = 1	1
SETB bit	bit = 1	1
CPL C	C = .NOT. C	1
CPL bit	bit = .NOT. bit	1
JC rel	Jump if C = 1	2
JNC rel	Jump if C = 0	2
JB bit,rel	Jump if bit = 1	2
JNB bit,rel	Jump if bit = 0	2
JBC bit,rel	Jump if bit = 1; CLR bit	2

The instruction set for the Boolean processor is shown in Table 7. All bit accesses are by direct addressing. Bit addresses 00H through 7FH are in the Lower 128, and bit addresses 80H through FFH are in SFR space.

Note how easily an internal flag can be moved to a port pin:

```
MOV    C,FLAG
MOV    P1.0,C
```

In this example, FLAG is the name of any addressable bit in the Lower 128 or SFR space. An I/O line (the LSB of Port 1, in this case) is set or cleared depending on whether the flag bit is 1 or 0.

The Carry bit in the PSW is used as the single-bit Accumulator of the Boolean processor. Bit instructions that refer to the Carry bit as C assemble as Carry-specific instructions (CLR C, etc). The Carry bit also has a direct address, since it resides in the PSW register, which is bit-addressable.

Note that the Boolean instruction set includes ANL and ORL operations, but not the XRL (Exclusive OR) operation. An XRL operation is simple to implement in software. Suppose, for example, it is required to form the Exclusive OR of two bits:

C = bit1 .XRL. bit2

The software to do that could be as follows:

```
MOV    C,bit1
JNB    bit2,OVER
CPL    C
```

OVER: (continue)

First, bit1 is moved to the Carry. If bit2 = 0, then C now contains the correct result. That is, bit1 .XRL. bit2 = bit1 if bit2 = 0. On the other hand, if bit2 = 1 C now contains the complement of the correct result. It need only be inverted (CPL C) to complete the operation.

This code uses the JNB instruction, one of a series of bit-test instructions which execute a jump if the addressed bit is set (JC, JB, JBC) or if the addressed bit is not set (JNC, JNB). In the above case, bit2 is being tested, and if bit2 = 0 the CPL C instruction is jumped over.

JBC executes the jump if the addressed bit is set, and also clears the bit. Thus a flag can be tested and cleared in one operation.

All the PSW bits are directly addressable, so the Parity bit, or the general purpose flags, for example, are also available to the bit-test instructions.

## RELATIVE OFFSET

The destination address for these jumps is specified to the assembler by a label or by an actual address in Program Memory. However, the destination address assembles to a relative offset byte. This is a signed (two's complement) offset byte which is added to the PC in two's complement arithmetic if the jump is executed.

The range of the jump is therefore -128 to +127 Program Memory bytes relative to the first byte following the instruction.

## Jump Instructions

Table 8 shows the list of unconditional jumps.

**Table 8. Unconditional Jumps  
in MCS<sup>®</sup>-51 Devices**

Mnemonic	Operation	Execution Time (μs)
JMP addr	Jump to addr	2
JMP @A+DPTR	Jump to A+DPTR	2
CALL addr	Call subroutine at addr	2
RET	Return from subroutine	2
RETI	Return from interrupt	2
NOP	No operation	1

The Table lists a single “JMP addr” instruction, but in fact there are three—SJMP, LJMP and AJMP—which differ in the format of the destination address. JMP is a generic mnemonic which can be used if the programmer does not care which way the jump is encoded.

The SJMP instruction encodes the destination address as a relative offset, as described above. The instruction is 2 bytes long, consisting of the opcode and the relative offset byte. The jump distance is limited to a range of -128 to +127 bytes relative to the instruction following the SJMP.

The LJMP instruction encodes the destination address as a 16-bit constant. The instruction is 3 bytes long, consisting of the opcode and two address bytes. The destination address can be anywhere in the 64K Program Memory space.

The AJMP instruction encodes the destination address as an 11-bit constant. The instruction is 2 bytes long, consisting of the opcode, which itself contains 3 of the 11 address bits, followed by another byte containing the low 8 bits of the destination address. When the instruction is executed, these 11 bits are simply substituted for the low 11 bits in the PC. The high 5 bits stay the same. Hence the destination has to be within the same 2K block as the instruction following the AJMP.

In all cases the programmer specifies the destination address to the assembler in the same way: as a label or as a 16-bit constant. The assembler will put the destination address into the correct format for the given instruction. If the format required by the instruction will not support the distance to the specified destination address, a “Destination out of range” message is written into the List file.

The JMP @A+DPTR instruction supports case jumps. The destination address is computed at execution time as the sum of the 16-bit DPTR register and

the Accumulator. Typically, DPTR is set up with the address of a jump table, and the Accumulator is given an index to the table. In a 5-way branch, for example, an integer 0 through 4 is loaded into the Accumulator. The code to be executed might be as follows:

```
MOV  DPTR, #JUMP_TABLE
MOV  A, INDEX_NUMBER
RL   A
JMP  @A+DPTR
```

The RL A instruction converts the index number (0 through 4) to an even number on the range 0 through 8, because each entry in the jump table is 2 bytes long:

```
JUMP_TABLE:
AJMP CASE_0
AJMP CASE_1
AJMP CASE_2
AJMP CASE_3
AJMP CASE_4
```

Table 8 shows a single “CALL addr” instruction, but there are two of them—LCALL and ACALL—which differ in the format in which the subroutine address is given to the CPU. CALL is a generic mnemonic which can be used if the programmer does not care which way the address is encoded.

The LCALL instruction uses the 16-bit address format, and the subroutine can be anywhere in the 64K Program Memory space. The ACALL instruction uses the 11-bit format, and the subroutine must be in the same 2K block as the instruction following the ACALL.

In any case the programmer specifies the subroutine address to the assembler in the same way: as a label or as a 16-bit constant. The assembler will put the address into the correct format for the given instructions.

Subroutines should end with a RET instruction, which returns execution to the instruction following the CALL.

RETI is used to return from an interrupt service routine. The only difference between RET and RETI is that RETI tells the interrupt control system that the interrupt in progress is done. If there is no interrupt in progress at the time RETI is executed, then the RETI is functionally identical to RET.

Table 9 shows the list of conditional jumps available to the MCS-51 user. All of these jumps specify the destination address by the relative offset method, and so are limited to a jump distance of -128 to +127 bytes from the instruction following the conditional jump instruction. Important to note, however, the user specifies to the assembler the actual destination address the same way as the other jumps: as a label or a 16-bit constant.

Table 9. Conditional Jumps in MCS®-51 Devices

Mnemonic	Operation	Addressing Modes				Execution Time (μs)
		Dir	Ind	Reg	Imm	
JZ rel	Jump if A = 0					2
JNZ rel	Jump if A ≠ 0					2
DJNZ <byte>,rel	Decrement and jump if not zero	X		X		2
CJNE A,<byte>,rel	Jump if A ≠ <byte>	X			X	2
CJNE <byte>,#data,rel	Jump if <byte> ≠ #data		X	X		2

There is no Zero bit in the PSW. The JZ and JNZ instructions test the Accumulator data for that condition.

The DJNZ instruction (Decrement and Jump if Not Zero) is for loop control. To execute a loop N times, load a counter byte with N and terminate the loop with a DJNZ to the beginning of the loop, as shown below for N = 10:

```

MOV    COUNTER,#10
LOOP:  (begin loop)
      *
      *
      *
      (end loop)
      DJNZ COUNTER,LOOP
      (continue)

```

The CJNE instruction (Compare and Jump if Not Equal) can also be used for loop control as in Figure 12. Two bytes are specified in the operand field of the instruction. The jump is executed only if the two bytes are not equal. In the example of Figure 12, the two bytes were the data in R1 and the constant 2AH. The initial data in R1 was 2EH. Every time the loop was executed, R1 was decremented, and the looping was to continue until the R1 data reached 2AH.

Another application of this instruction is in “greater than, less than” comparisons. The two bytes in the operand field are taken as unsigned integers. If the first is less than the second, then the Carry bit is set (1). If the first is greater than or equal to the second, then the Carry bit is cleared.

## CPU TIMING

All MCS-51 microcontrollers have an on-chip oscillator which can be used if desired as the clock source for the CPU. To use the on-chip oscillator, connect a crystal or ceramic resonator between the XTAL1 and XTAL2 pins of the microcontroller, and capacitors to ground as shown in Figure 13.

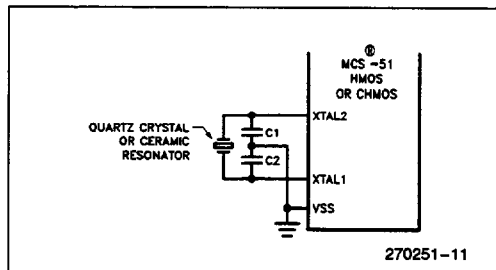

Figure 13. Using the On-Chip Oscillator

Figure 14. Using an External Clock

Examples of how to drive the clock with an external oscillator are shown in Figure 14. Note that in the HMOS devices (8051, etc.) the signal at the XTAL2 pin actually drives the internal clock generator. In the CHMOS devices (80C51BH, etc.) the signal at the XTAL1 pin drives the internal clock generator. If only one pin is going to be driven with the external oscillator signal, make sure it is the right pin.

The internal clock generator defines the sequence of states that make up the MCS-51 machine cycle.

## Machine Cycles

A machine cycle consists of a sequence of 6 states, numbered S1 through S6. Each state time lasts for two oscillator periods. Thus a machine cycle takes 12 oscillator periods or 1  $\mu$ s if the oscillator frequency is 12 MHz.

Each state is divided into a Phase 1 half and a Phase 2 half. Figure 15 shows the fetch/execute sequences in

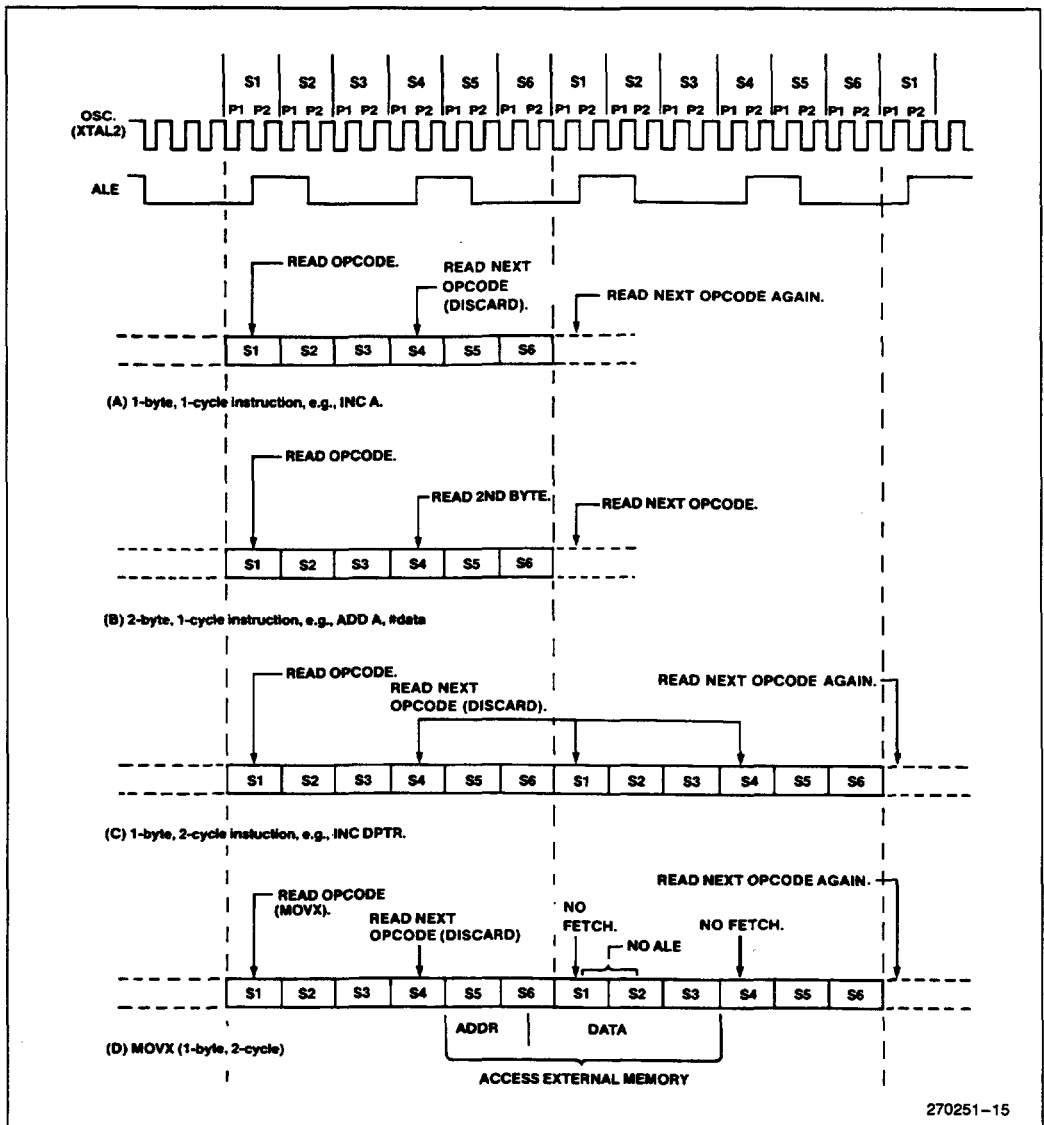

Figure 15. State Sequences in MCS®-51 Devices

states and phases for various kinds of instructions. Normally two program fetches are generated during each machine cycle, even if the instruction being executed doesn't require it. If the instruction being executed doesn't need more code bytes, the CPU simply ignores the extra fetch, and the Program Counter is not incremented.

Execution of a one-cycle instruction (Figure 15A and B) begins during State 1 of the machine cycle, when the opcode is latched into the Instruction Register. A second fetch occurs during S4 of the same machine cycle. Execution is complete at the end of State 6 of this machine cycle.

The MOVX instructions take two machine cycles to execute. No program fetch is generated during the second cycle of a MOVX instruction. This is the only time program fetches are skipped. The fetch/execute sequence for MOVX instructions is shown in Figure 15(D).

The fetch/execute sequences are the same whether the Program Memory is internal or external to the chip. Execution times do not depend on whether the Program Memory is internal or external.

Figure 16 shows the signals and timing involved in program fetches when the Program Memory is external. If Program Memory is external, then the Program Memory read strobe  $\overline{\text{PSEN}}$  is normally activated twice per machine cycle, as shown in Figure 16(A).

If an access to external Data Memory occurs, as shown in Figure 16(B), two  $\overline{\text{PSEN}}$ s are skipped, because the address and data bus are being used for the Data Memory access.

Note that a Data Memory bus cycle takes twice as much time as a Program Memory bus cycle. Figure 16 shows the relative timing of the addresses being emitted at Ports 0 and 2, and of ALE and  $\overline{\text{PSEN}}$ . ALE is used to latch the low address byte from P0 into the address latch.

Figure 16. Bus Cycles in MCS®-51 Devices Executing from External Program Memory

When the CPU is executing from internal Program Memory, PSEN is not activated, and program addresses are not emitted. However, ALE continues to be activated twice per machine cycle and so is available as a clock output signal. Note, however, that one ALE is skipped during the execution of the MOVX instruction.

## Interrupt Structure

The 8051 core provides 5 interrupt sources: 2 external interrupts, 2 timer interrupts, and the serial port interrupt. What follows is an overview of the interrupt structure for the 8051. Other MCS-51 devices have additional interrupt sources and vectors as shown in Table 1. Refer to the appropriate chapters on other devices for further information on their interrupts.

## INTERRUPT ENABLES

Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the SFR

**Figure 17. IE (Interrupt Enable) Register in the 8051**

named IE (Interrupt Enable). This register also contains a global disable bit, which can be cleared to disable all interrupts at once. Figure 17 shows the IE register for the 8051.

## INTERRUPT PRIORITIES

Each interrupt source can also be individually programmed to one of two priority levels by setting or clearing a bit in the SFR named IP (Interrupt Priority). Figure 18 shows the IP register in the 8051.

A low-priority interrupt can be interrupted by a high-priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence.

Figure 19 shows, for the 8051, how the IE and IP registers and the polling sequence work to determine which if any interrupt will be serviced.

**Figure 18. IP (Interrupt Priority) Register in the 8051**

Figure 19. 8051 Interrupt Control System

In operation, all the interrupt flags are latched into the interrupt control system during State 5 of every machine cycle. The samples are polled during the following machine cycle. If the flag for an enabled interrupt is found to be set (1), the interrupt system generates an LCALL to the appropriate location in Program Memory, unless some other condition blocks the interrupt. Several conditions can block an interrupt, among them that an interrupt of equal or higher priority level is already in progress.

The hardware-generated LCALL causes the contents of the Program Counter to be pushed onto the stack, and reloads the PC with the beginning address of the service routine. As previously noted (Figure 3), the service routine for each interrupt begins at a fixed location.

Only the Program Counter is automatically pushed onto the stack, not the PSW or any other register. Having only the PC be automatically saved allows the programmer to decide how much time to spend saving which other registers. This enhances the interrupt response time, albeit at the expense of increasing the programmer's burden of responsibility. As a result, many interrupt functions that are typical in control applications—toggling a port pin, for example, or reloading a timer, or unloading a serial buffer—can often be com-

pleted in less time than it takes other architectures to commence them.

### SIMULATING A THIRD PRIORITY LEVEL IN SOFTWARE

Some applications require more than the two priority levels that are provided by on-chip hardware in MCS-51 devices. In these cases, relatively simple software can be written to produce the same effect as a third priority level.

First, interrupts that are to have higher priority than 1 are assigned to priority 1 in the IP (Interrupt Priority) register. The service routines for priority 1 interrupts that are supposed to be interruptible by "priority 2" interrupts are written to include the following code:

```

PUSH    IE
MOV     IE, #MASK
CALL    LABEL
.....
(execute service routine)
.....
POP     IE
RET
LABEL: RETI

```

As soon as any priority 1 interrupt is acknowledged, the IE (Interrupt Enable) register is re-defined so as to disable all but "priority 2" interrupts. Then, a CALL to LABEL executes the RETI instruction, which clears the priority 1 interrupt-in-progress flip-flop. At this point any priority 1 interrupt that is enabled can be serviced, but only "priority 2" interrupts are enabled.

POPPing IE restores the original enable byte. Then a normal RET (rather than another RETI) is used to terminate the service routine. The additional software adds 10  $\mu$ s (at 12 MHz) to priority 1 interrupts.

The information presented in this chapter is collected from the MCS®-51 Architectural Overview and the Hardware Description of the 8051, 8052 and 80C51 chapters of this book. The material has been selected and rearranged to form a quick and convenient reference for the programmers of the MCS-51. This guide pertains specifically to the 8051, 8052 and 80C51.

## MEMORY ORGANIZATION

### PROGRAM MEMORY

The 8051 has separate address spaces for Program Memory and Data Memory. The Program Memory can be up to 64K bytes long. The lower 4K (8K for the 8052) may reside on-chip.

Figure 1 shows a map of the 8051 program memory, and Figure 2 shows a map of the 8052 program memory.

Figure 1. The 8051 Program Memory

**Figure 2. The 8052 Program Memory**

### Data Memory:

The 8051 can address up to 64K bytes of Data Memory external to the chip. The "MOVX" instruction is used to access the external data memory. (Refer to the MCS-51 Instruction Set, in this chapter, for detailed description of instructions).

The 8051 has 128 bytes of on-chip RAM (256 bytes in the 8052) plus a number of Special Function Registers (SFRs). The lower 128 bytes of RAM can be accessed either by direct addressing (MOV data addr) or by indirect addressing (MOV @Ri). Figure 3 shows the 8051 and the 8052 Data Memory organization.

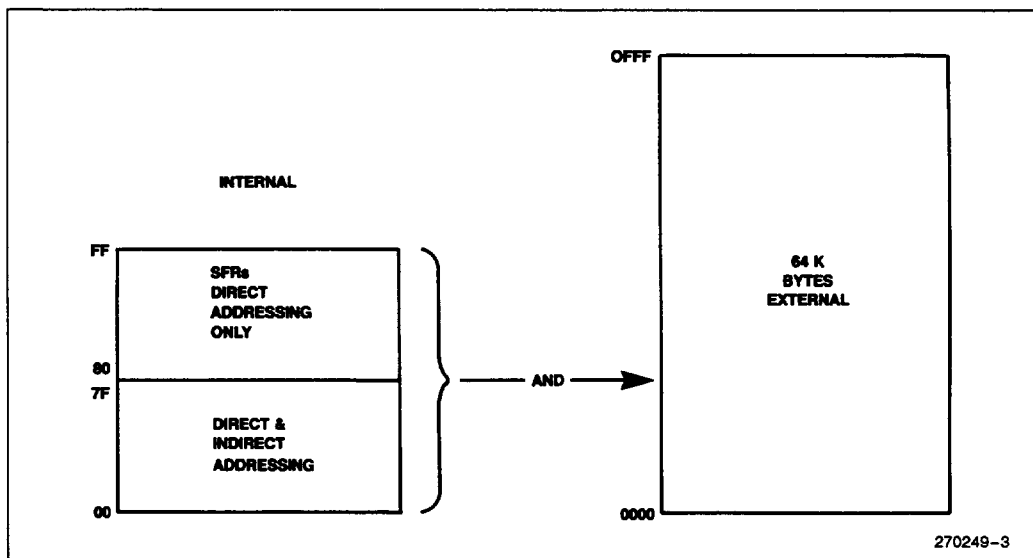

Figure 3a. The 8051 Data Memory

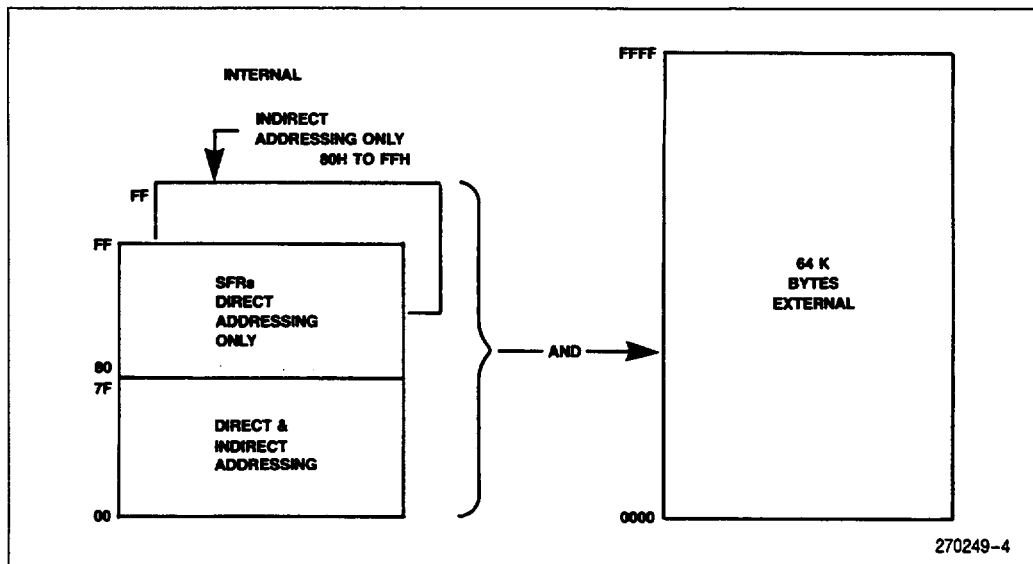

Figure 3b. The 8052 Data Memory

## INDIRECT ADDRESS AREA:

Note that in Figure 3b the SFRs and the indirect address RAM have the same addresses (80H–0FFH). Nevertheless, they are two separate areas and are accessed in two different ways.

For example the instruction

```
MOV    80H, #0AAH
```

writes 0AAH to Port 0 which is one of the SFRs and the instruction

```
MOV    R0, #80H
```

```
MOV    @R0, #0BBH
```

writes 0BBH in location 80H of the data RAM. Thus, after execution of both of the above instructions Port 0 will contain 0AAH and location 80 of the RAM will contain 0BBH.

Note that the stack operations are examples of indirect addressing, so the upper 128 bytes of data RAM are available as stack space in those devices which implement 256 bytes of internal RAM.

## DIRECT AND INDIRECT ADDRESS AREA:

The 128 bytes of RAM which can be accessed by both direct and indirect addressing can be divided into 3 segments as listed below and shown in Figure 4.

**1. Register Banks 0-3:** Locations 0 through 1FH (32 bytes). ASM-51 and the device after reset default to register bank 0. To use the other register banks the user must select them in the software (refer to the MCS-51 Micro Assembler User's Guide). Each register bank contains 8 one-byte registers, 0 through 7.

Reset initializes the Stack Pointer to location 07H and it is incremented once to start from location 08H which is the first register (R0) of the second register bank. Thus, in order to use more than one register bank, the SP should be initialized to a different location of the RAM where it is not used for data storage (ie, higher part of the RAM).

**2. Bit Addressable Area:** 16 bytes have been assigned for this segment, 20H-2FH. Each one of the 128 bits of this segment can be directly addressed (0-7FH).

The bits can be referred to in two ways both of which are acceptable by the ASM-51. One way is to refer to their addresses, ie. 0 to 7FH. The other way is with reference to bytes 20H to 2FH. Thus, bits 0–7 can also be referred to as bits 20.0–20.7, and bits 8–FH are the same as 21.0–21.7 and so on.

Each of the 16 bytes in this segment can also be addressed as a byte.

**3. Scratch Pad Area:** Bytes 30H through 7FH are available to the user as data RAM. However, if the stack pointer has been initialized to this area, enough number of bytes should be left aside to prevent SP data destruction.

Figure 4 shows the different segments of the on-chip RAM.

Figure 4. 128 Bytes of RAM Direct and Indirect Addressable

**SPECIAL FUNCTION REGISTERS:**

Table 1 contains a list of all the SFRs and their addresses.

Comparing Table 1 and Figure 5 shows that all of the SFRs that are byte and bit addressable are located on the first column of the diagram in Figure 5.

**Table 1**

Symbol	Name	Address

Addressable

Figure 5

Those SFRs that have their bits assigned for various functions are listed in this section. A brief description of each bit is provided for quick reference. For more detailed information refer to the Architecture Chapter of this book.

### PSW: PROGRAM STATUS WORD. BIT ADDRESSABLE.

CY	AC	F0	RS1	RS0	OV	—	P
----	----	----	-----	-----	----	---	---

CY	PSW.7	Carry Flag.
AC	PSW.6	Auxiliary Carry Flag.
F0	PSW.5	Flag 0 available to the user for general purpose.
RS1	PSW.4	Register Bank selector bit 1 (SEE NOTE 1).
RS0	PSW.3	Register Bank selector bit 0 (SEE NOTE 1).
OV	PSW.2	Overflow Flag.
—	PSW.1	User definable flag.
P	PSW.0	Parity flag. Set/cleared by hardware each instruction cycle to indicate an odd/even number of '1' bits in the accumulator.

#### NOTE:

1. The value presented by RS0 and RS1 selects the corresponding register bank.

RS1	RS0	Register Bank	Address
0	0	0	00H-07H
0	1	1	08H-0FH
1	0	2	10H-17H
1	1	3	18H-1FH

### PCON: POWER CONTROL REGISTER. NOT BIT ADDRESSABLE.

SMOD	—	—	—	GF1	GF0	PD	IDL
------	---	---	---	-----	-----	----	-----

**SMOD** Double baud rate bit. If Timer 1 is used to generate baud rate and SMOD = 1, the baud rate is doubled when the Serial Port is used in modes 1, 2, or 3.

— Not implemented, reserved for future use.\*

— Not implemented, reserved for future use.\*

— Not implemented, reserved for future use.\*

**GF1** General purpose flag bit.

**GF0** General purpose flag bit.

**PD** Power Down bit. Setting this bit activates Power Down operation in the 80C51BH. (Available only in CHMOS).

**IDL** Idle Mode bit. Setting this bit activates Idle Mode operation in the 80C51BH. (Available only in CHMOS).

If 1s are written to PD and IDL at the same time, PD takes precedence.

\*User software should not write 1s to reserved bits. These bits may be used in future MCS-51 products to invoke new features. In that case, the reset or inactive value of the new bit will be 0, and its active value will be 1.

**INTERRUPTS:**

In order to use any of the interrupts in the MCS-51, the following three steps must be taken.

1. Set the EA (enable all) bit in the IE register to 1.
2. Set the corresponding individual interrupt enable bit in the IE register to 1.
3. Begin the interrupt service routine at the corresponding Vector Address of that interrupt. See Table below.

Interrupt Source	Vector Address
IE0	0003H
TF0	000BH
IE1	0013H
TF1	001BH
RI & TI	0023H
TF2 & EXF2	002BH

In addition, for external interrupts, pins  $\overline{\text{INT0}}$  and  $\overline{\text{INT1}}$  (P3.2 and P3.3) must be set to 1, and depending on whether the interrupt is to be level or transition activated, bits IT0 or IT1 in the TCON register may need to be set to 1.

ITx = 0 level activated

ITx = 1 transition activated

**IE: INTERRUPT ENABLE REGISTER. BIT ADDRESSABLE.**

If the bit is 0, the corresponding interrupt is disabled. If the bit is 1, the corresponding interrupt is enabled.

EA	—	ET2	ES	ET1	EX1	ET0	EX0
----	---	-----	----	-----	-----	-----	-----

EA	IE.7	Disables all interrupts. If EA = 0, no interrupt will be acknowledged. If EA = 1, each interrupt source is individually enabled or disabled by setting or clearing its enable bit.
—	IE.6	Not implemented, reserved for future use.*
ET2	IE.5	Enable or disable the Timer 2 overflow or capture interrupt (8052 only).
ES	IE.4	Enable or disable the serial port interrupt.
ET1	IE.3	Enable or disable the Timer 1 overflow interrupt.
EX1	IE.2	Enable or disable External Interrupt 1.
ET0	IE.1	Enable or disable the Timer 0 overflow interrupt.
EX0	IE.0	Enable or disable External Interrupt 0.

\*User software should not write 1s to reserved bits. These bits may be used in future MCS-51 products to invoke new features. In that case, the reset or inactive value of the new bit will be 0, and its active value will be 1.

## ASSIGNING HIGHER PRIORITY TO ONE OR MORE INTERRUPTS:

In order to assign higher priority to an interrupt the corresponding bit in the IP register must be set to 1.

Remember that while an interrupt service is in progress, it cannot be interrupted by a lower or same level interrupt.

## PRIORITY WITHIN LEVEL:

Priority within level is only to resolve simultaneous requests of the same priority level.

From high to low, interrupt sources are listed below:

IE0  
TF0  
IE1  
TF1  
RI or TI  
TF2 or EXF2

## IP: INTERRUPT PRIORITY REGISTER. BIT ADDRESSABLE.

If the bit is 0, the corresponding interrupt has a lower priority and if the bit is 1 the corresponding interrupt has a higher priority.

—	—	PT2	PS	PT1	PX1	PT0	PX0
---	---	-----	----	-----	-----	-----	-----

- IP. 7 Not implemented, reserved for future use.\*
- IP. 6 Not implemented, reserved for future use.\*
- PT2 IP. 5 Defines the Timer 2 interrupt priority level (8052 only).
- PS IP. 4 Defines the Serial Port interrupt priority level.
- PT1 IP. 3 Defines the Timer 1 interrupt priority level.
- PX1 IP. 2 Defines External Interrupt 1 priority level.
- PT0 IP. 1 Defines the Timer 0 interrupt priority level.
- PX0 IP. 0 Defines the External Interrupt 0 priority level.

\*User software should not write 1s to reserved bits. These bits may be used in future MCS-51 products to invoke new features. In that case, the reset or inactive value of the new bit will be 0, and its active value will be 1.

**TCON: TIMER/COUNTER CONTROL REGISTER. BIT ADDRESSABLE.**

TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0
-----	-----	-----	-----	-----	-----	-----	-----

- TF1** TCON. 7 Timer 1 overflow flag. Set by hardware when the Timer/Counter 1 overflows. Cleared by hardware as processor vectors to the interrupt service routine.
- TR1** TCON. 6 Timer 1 run control bit. Set/cleared by software to turn Timer/Counter 1 ON/OFF.
- TF0** TCON. 5 Timer 0 overflow flag. Set by hardware when the Timer/Counter 0 overflows. Cleared by hardware as processor vectors to the service routine.
- TR0** TCON. 4 Timer 0 run control bit. Set/cleared by software to turn Timer/Counter 0 ON/OFF.
- IE1** TCON. 3 External Interrupt 1 edge flag. Set by hardware when External Interrupt edge is detected. Cleared by hardware when interrupt is processed.
- IT1** TCON. 2 Interrupt 1 type control bit. Set/cleared by software to specify falling edge/low level triggered External Interrupt.
- IE0** TCON. 1 External Interrupt 0 edge flag. Set by hardware when External Interrupt edge detected. Cleared by hardware when interrupt is processed.
- IT0** TCON. 0 Interrupt 0 type control bit. Set/cleared by software to specify falling edge/low level triggered External Interrupt.

**TMOD: TIMER/COUNTER MODE CONTROL REGISTER. NOT BIT ADDRESSABLE.**

GATE	C/ $\bar{T}$	M1	M0	GATE	C/ $\bar{T}$	M1	M0
------	--------------	----	----	------	--------------	----	----

**TIMER 1****TIMER 0**

- GATE** When TR<sub>x</sub> (in TCON) is set and GATE = 1, TIMER/COUNTER<sub>x</sub> will run only while INT<sub>x</sub> pin is high (hardware control). When GATE = 0, TIMER/COUNTER<sub>x</sub> will run only while TR<sub>x</sub> = 1 (software control).
- C/ $\bar{T}$**  Timer or Counter selector. Cleared for Timer operation (input from internal system clock). Set for Counter operation (input from Tx input pin).
- M1** Mode selector bit. (NOTE 1)
- M0** Mode selector bit. (NOTE 1)

**NOTE 1:**

M1	M0	Operating Mode	
0	0	0	13-bit Timer (MCS-48 compatible)
0	1	1	16-bit Timer/Counter
1	0	2	8-bit Auto-Reload Timer/Counter
1	1	3	(Timer 0) TL0 is an 8-bit Timer/Counter controlled by the standard Timer 0 control bits, TH0 is an 8-bit Timer and is controlled by Timer 0 control bits.
1	1	3	(Timer 1) Timer/Counter 1 stopped.

## TIMER SET-UP

Tables 3 through 6 give some values for TMOD which can be used to set up Timer 0 in different modes.

It is assumed that only one timer is being used at a time. If it is desired to run Timers 0 and 1 simultaneously, in any mode, the value in TMOD for Timer 0 must be ORed with the value shown for Timer 1 (Tables 5 and 6).

For example, if it is desired to run Timer 0 in mode 1 GATE (external control), and Timer 1 in mode 2 COUNTER, then the value that must be loaded into TMOD is 69H (09H from Table 3 ORed with 60H from Table 6).

Moreover, it is assumed that the user, at this point, is not ready to turn the timers on and will do that at a different point in the program by setting bit TRx (in TCON) to 1.

## TIMER/COUNTER 0

### As a Timer:

Table 3

MODE	TIMER 0 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	00H	08H
1	16-bit Timer	01H	09H
2	8-bit Auto-Reload	02H	0AH
3	two 8-bit Timers	03H	0BH

### As a Counter:

Table 4

MODE	COUNTER 0 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	04H	0CH
1	16-bit Timer	05H	0DH
2	8-bit Auto-Reload	06H	0EH
3	one 8-bit Counter	07H	0FH

#### NOTES:

1. The Timer is turned ON/OFF by setting/clearing bit TR0 in the software.
2. The Timer is turned ON/OFF by the 1 to 0 transition on INT0 (P3.2) when TR0 = 1 (hardware control).

**TIMER/COUNTER 1****As a Timer:****Table 5**

MODE	TIMER 1 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	00H	80H
1	16-bit Timer	10H	90H
2	8-bit Auto-Reload	20H	A0H
3	does not run	30H	B0H

**As a Counter:****Table 6**

MODE	COUNTER 1 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	40H	C0H
1	16-bit Timer	50H	D0H
2	8-bit Auto-Reload	60H	E0H
3	not available	—	—

**NOTES:**

1. The Timer is turned ON/OFF by setting/clearing bit TR1 in the software.
2. The Timer is turned ON/OFF by the 1 to 0 transition on  $\overline{\text{INT1}}$  (P3.3) when TR1 = 1 (hardware control).

**T2CON: TIMER/COUNTER 2 CONTROL REGISTER. BIT ADDRESSABLE****8052 Only**

TF2	EXF2	RCLK	TCLK	EXEN2	TR2	C/ $\overline{T2}$	CP/ $\overline{RL2}$
-----	------	------	------	-------	-----	--------------------	----------------------

TF2	T2CON. 7	Timer 2 overflow flag set by hardware and cleared by software. TF2 cannot be set when either RCLK = 1 or CLK = 1					
EXF2	T2CON. 6	Timer 2 external flag set when either a capture or reload is caused by a negative transition on T2EX, and EXEN2 = 1. When Timer 2 interrupt is enabled, EXF2 = 1 will cause the CPU to vector to the Timer 2 interrupt routine. EXF2 must be cleared by software.					
RCLK	T2CON. 5	Receive clock flag. When set, causes the Serial Port to use Timer 2 overflow pulses for its receive clock in modes 1 & 3. RCLK = 0 causes Timer 1 overflow to be used for the receive clock.					
TCLK	T2CON. 4	Transmit clock flag. When set, causes the Serial Port to use Timer 2 overflow pulses for its transmit clock in modes 1 & 3. TCLK = 0 causes Timer 1 overflows to be used for the transmit clock.					
EXEN2	T2CON. 3	Timer 2 external enable flag. When set, allows a capture or reload to occur as a result of negative transition on T2EX if Timer 2 is not being used to clock the Serial Port. EXEN2 = 0 causes Timer 2 to ignore events at T2EX.					
TR2	T2CON. 2	Software START/STOP control for Timer 2. A logic 1 starts the Timer.					
C/ $\overline{T2}$	T2CON. 1	Timer or Counter select. 0 = Internal Timer. 1 = External Event Counter (falling edge triggered).					
CP/ $\overline{RL2}$	T2CON. 0	Capture/Reload flag. When set, captures will occur on negative transitions at T2EX if EXEN2 = 1. When cleared, Auto-Reloads will occur either with Timer 2 overflows or negative transitions at T2EX when EXEN2 = 1. When either RCLK = 1 or TCLK = 1, this bit is ignored and the Timer is forced to Auto-Reload on Timer 2 overflow.					

## TIMER/COUNTER 2 SET-UP

Except for the baud rate generator mode, the values given for T2CON do not include the setting of the TR2 bit. Therefore, bit TR2 must be set, separately, to turn the Timer on.

### As a Timer:

**Table 7**

MODE	T2CON	
	INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
16-bit Auto-Reload	00H	08H
16-bit Capture	01H	09H
BAUD rate generator receive & transmit same baud rate	34H	36H
receive only	24H	26H
transmit only	14H	16H

### As a Counter:

**Table 8**

MODE	TMOD	
	INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
16-bit Auto-Reload	02H	0AH
16-bit Capture	03H	0BH

#### NOTES:

1. Capture/Reload occurs only on Timer/Counter overflow.
2. Capture/Reload occurs on Timer/Counter overflow and a 1 to 0 transition on T2EX (P1.1) pin except when Timer 2 is used in the baud rate generating mode.

**SCON: SERIAL PORT CONTROL REGISTER. BIT ADDRESSABLE.**

SM0	SM1	SM2	REN	TB8	RB8	TI	RI
-----	-----	-----	-----	-----	-----	----	----

SM0	SCON. 7	Serial Port mode specifier. (NOTE 1).					
SM1	SCON. 6	Serial Port mode specifier. (NOTE 1).					
SM2	SCON. 5	Enables the multiprocessor communication feature in modes 2 & 3. In mode 2 or 3, if SM2 is set to 1 then RI will not be activated if the received 9th data bit (RB8) is 0. In mode 1, if SM2 = 1 then RI will not be activated if a valid stop bit was not received. In mode 0, SM2 should be 0. (See Table 9).					
REN	SCON. 4	Set/Cleared by software to Enable/Disable reception.					
TB8	SCON. 3	The 9th bit that will be transmitted in modes 2 & 3. Set/Cleared by software.					
RB8	SCON. 2	In modes 2 & 3, is the 9th data bit that was received. In mode 1, if SM2 = 0, RB8 is the stop bit that was received. In mode 0, RB8 is not used.					
TI	SCON. 1	Transmit interrupt flag. Set by hardware at the end of the 8th bit time in mode 0, or at the beginning of the stop bit in the other modes. Must be cleared by software.					
RI	SCON. 0	Receive interrupt flag. Set by hardware at the end of the 8th bit time in mode 0, or halfway through the stop bit time in the other modes (except see SM2). Must be cleared by software.					

**NOTE 1:**

SM0	SM1	Mode	Description	Baud Rate
0	0	0	SHIFT REGISTER	Fosc./12
0	1	1	8-Bit UART	Variable
1	0	2	9-Bit UART	Fosc./64 OR Fosc./32
1	1	3	9-Bit UART	Variable

**SERIAL PORT SET-UP:**

Table 9

MODE	SCON	SM2 VARIATION
0	10H	Single Processor Environment (SM2 = 0)
1	50H	
2	90H	
3	D0H	
0	NA	Multiprocessor Environment (SM2 = 1)
1	70H	
2	B0H	
3	F0H	

**GENERATING BAUD RATES****Serial Port in Mode 0:**

Mode 0 has a fixed baud rate which is 1/12 of the oscillator frequency. To run the serial port in this mode none of the Timer/Counters need to be set up. Only the SCON register needs to be defined.

$$\text{Baud Rate} = \frac{\text{Osc Freq}}{12}$$

**Serial Port in Mode 1:**

Mode 1 has a variable baud rate. The baud rate can be generated by either Timer 1 or Timer 2 (8052 only).

## USING TIMER/COUNTER 1 TO GENERATE BAUD RATES:

For this purpose, Timer 1 is used in mode 2 (Auto-Reload). Refer to Timer Setup section of this chapter.

$$\text{Baud Rate} = \frac{K \times \text{Oscillator Freq.}}{32 \times 12 \times [256 - (\text{TH1})]}$$

If SMOD = 0, then K = 1.

If SMOD = 1, then K = 2. (SMOD is the PCON register).

Most of the time the user knows the baud rate and needs to know the reload value for TH1.

Therefore, the equation to calculate TH1 can be written as:

$$\text{TH1} = 256 - \frac{K \times \text{Osc Freq.}}{384 \times \text{baud rate}}$$

TH1 must be an integer value. Rounding off TH1 to the nearest integer may not produce the desired baud rate. In this case, the user may have to choose another crystal frequency.

Since the PCON register is not bit addressable, one way to set the bit is logical ORing the PCON register. (ie, ORL PCON, #80H). The address of PCON is 87H.

## USING TIMER/COUNTER 2 TO GENERATE BAUD RATES:

For this purpose, Timer 2 must be used in the baud rate generating mode. Refer to Timer 2 Setup Table in this chapter. If Timer 2 is being clocked through pin T2 (P1.0) the baud rate is:

$$\text{Baud Rate} = \frac{\text{Timer 2 Overflow Rate}}{16}$$

And if it is being clocked internally the baud rate is:

$$\text{Baud Rate} = \frac{\text{Osc Freq}}{32 \times [65536 - (\text{RCAP2H}, \text{RCAP2L})]}$$

To obtain the reload value for RCAP2H and RCAP2L the above equation can be rewritten as:

$$\text{RCAP2H}, \text{RCAP2L} = 65536 - \frac{\text{Osc Freq}}{32 \times \text{Baud Rate}}$$

## SERIAL PORT IN MODE 2:

The baud rate is fixed in this mode and is  $\frac{1}{32}$  or  $\frac{1}{64}$  of the oscillator frequency depending on the value of the SMOD bit in the PCON register.

In this mode none of the Timers are used and the clock comes from the internal phase 2 clock.

SMOD = 1, Baud Rate =  $\frac{1}{32}$  Osc Freq.

SMOD = 0, Baud Rate =  $\frac{1}{64}$  Osc Freq.

To set the SMOD bit: ORL PCON, #80H. The address of PCON is 87H.

## SERIAL PORT IN MODE 3:

The baud rate in mode 3 is variable and sets up exactly the same as in mode 1.

# **MCS®-51 INSTRUCTION SET**

**Table 10. 8051 Instruction Set Summary**

Interrupt Response Time: Refer to Hardware Description Chapter.							
Instructions that Affect Flag Settings <sup>(1)</sup>							
Instruction	Flag			Instruction	Flag		
	C	OV	AC		C	OV	AC
ADD	X	X	X	CLR C	O		
ADDC	X	X	X	CPL C	X		
SUBB	X	X	X	ANL C,bit	X		
MUL	O	X		ANL C,/bit	X		
DIV	O	X		ORL C,bit	X		
DA	X			ORL C,bit	X		
RRC	X			MOV C,bit	X		
RLC	X			CJNE	X		
SETB C	1						

(1)Note that operations on SFR byte address 208 or bit addresses 209-215 (i.e., the PSW or bits in the PSW) will also affect flag settings.

**Note on instruction set and addressing modes:**

**Rn** — Register R7–R0 of the currently selected Register Bank.

**direct** — 8-bit internal data location's address. This could be an Internal Data RAM location (0–127) or a SFR [i.e., I/O port, control register, status register, etc. (128–255)].

**@Ri** — 8-bit internal data RAM location (0–255) addressed indirectly through register R1 or R0.

**#data** — 8-bit constant included in instruction.

**#data 16** — 16-bit constant included in instruction.

**addr 16** — 16-bit destination address. Used by LCALL & LJMP. A branch can be anywhere within the 64K-byte Program Memory address space.

**addr 11** — 11-bit destination address. Used by ACALL & AJMP. The branch will be within the same 2K-byte page of program memory as the first byte of the following instruction.

**rel** — Signed (two's complement) 8-bit offset byte. Used by SJMP and all conditional jumps. Range is –128 to +127 bytes relative to first byte of the following instruction.

**bit** — Direct Addressed bit in Internal Data RAM or Special Function Register.

Mnemonic	Description	Byte	Oscillator Period
<b>ARITHMETIC OPERATIONS</b>			
ADD A,Rn	Add register to Accumulator	1	12

## INSTRUCTION DEFINITIONS

### ACALL addr11

**Function:** Absolute Call

**Description:** ACALL unconditionally calls a subroutine located at the indicated address. The instruction increments the PC twice to obtain the address of the following instruction, then pushes the 16-bit result onto the stack (low-order byte first) and increments the Stack Pointer twice. The destination address is obtained by successively concatenating the five high-order bits of the incremented PC, opcode bits 7-5, and the second byte of the instruction. The subroutine called must therefore start within the same 2K block of the program memory as the first byte of the instruction following ACALL. No flags are affected.

**Example:** Initially SP equals 07H. The label "SUBRTN" is at program memory location 0345 H. After executing the instruction,

ACALL SUBRTN

at location 0123H, SP will contain 09H, internal RAM locations 08H and 09H will contain 25H and 01H, respectively, and the PC will contain 0345H.

**Bytes:** 2

**Cycles:** 2

**Encoding:**

a10	a9	a8	1	0	0	0	1
-----	----	----	---	---	---	---	---

a7	a6	a5	a4	a3	a2	a1	a0
----	----	----	----	----	----	----	----

**Operation:**

ACALL  
 $(PC) \leftarrow (PC) + 2$   
 $(SP) \leftarrow (SP) + 1$   
 $((SP)) \leftarrow (PC_{7-0})$   
 $(SP) \leftarrow (SP) + 1$   
 $((SP)) \leftarrow (PC_{15-8})$   
 $(PC_{10-0}) \leftarrow \text{page address}$

**ADD A,<src-byte>****Function:** Add

**Description:** ADD adds the byte variable indicated to the Accumulator, leaving the result in the Accumulator. The carry and auxiliary-carry flags are set, respectively, if there is a carry-out from bit 7 or bit 3, and cleared otherwise. When adding unsigned integers, the carry flag indicates an overflow occurred.

OV is set if there is a carry-out of bit 6 but not out of bit 7, or a carry-out of bit 7 but not bit 6; otherwise OV is cleared. When adding signed integers, OV indicates a negative number produced as the sum of two positive operands, or a positive sum from two negative operands.

Four source operand addressing modes are allowed: register, direct, register-indirect, or immediate.

**Example:** The Accumulator holds 0C3H (11000011B) and register 0 holds 0AAH (10101010B). The instruction,

```
ADD A,R0
```

will leave 6DH (01101101B) in the Accumulator with the AC flag cleared and both the carry flag and OV set to 1.

**ADD A,Rn****Bytes:** 1**Cycles:** 1

**Encoding:**

0	0	1	0
---	---	---	---

1	r	r	r
---	---	---	---

**Operation:** ADD  
 $(A) \leftarrow (A) + (Rn)$

**ADD A,direct****Bytes:** 2**Cycles:** 1

immediate data			
----------------	--	--	--

**Operation:** ADD  
 $(A) \leftarrow (A) + \#data$ **ADDC A,<src-byte>**

---

**Function:** Add with Carry**Description:** ADCc simultaneously adds the byte variable indicated, the carry flag and the Accumulator contents, leaving the result in the Accumulator. The carry and auxiliary-carry flags are set, respectively, if there is a carry-out from bit 7 or bit 3, and cleared otherwise. When adding unsigned integers, the carry flag indicates an overflow occurred.

OV is set if there is a carry-out of bit 6 but not out of bit 7, or a carry-out of bit 7 but not out of bit 6; otherwise OV is cleared. When adding signed integers, OV indicates a negative number produced as the sum of two positive operands or a positive sum from two negative operands.

Four source operand addressing modes are allowed: register, direct, register-indirect, or immediate.

**Example:** The Accumulator holds 0C3H (11000011B) and register 0 holds 0AAH (10101010B) with the carry flag set. The instruction,

ADDC A,R0

will leave 6EH (01101110B) in the Accumulator with AC cleared and both the Carry flag and OV set to 1.

**AJMP addr11****Function:** Absolute Jump**Description:** AJMP transfers program execution to the indicated address, which is formed at run-time by concatenating the high-order five bits of the PC (*after* incrementing the PC twice), opcode bits 7-5, and the second byte of the instruction. The destination must therefore be within the same 2K block of program memory as the first byte of the instruction following AJMP.**Example:** The label "JMPADR" is at program memory location 0123H. The instruction,

AJMP JMPADR

is at location 0345H and will load the PC with 0123H.

**Bytes:** 2**Cycles:** 2**Encoding:**

a10	a9	a8	0	0	0	0	1
-----	----	----	---	---	---	---	---

a7	a6	a5	a4	a3	a2	a1	a0
----	----	----	----	----	----	----	----

**Operation:**

AJMP

 $(PC) \leftarrow (PC) + 2$  $(PC_{10-0}) \leftarrow \text{page address}$ **ANL <dest-byte>, <src-byte>****Function:** Logical-AND for byte variables**Description:** ANL performs the bitwise logical-AND operation between the variables indicated and stores the results in the destination variable. No flags are affected.

The two operands allow six addressing mode combinations. When the destination is the Accumulator, the source can use register, direct, register-indirect, or immediate addressing; when the destination is a direct address, the source can be the Accumulator or immediate data.

*Note:* When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.

**Example:** If the Accumulator holds 0C3H (11000011B) and register 0 holds 55H (01010101B) then the instruction,

ANL A,R0

will leave 41H (0100001B) in the Accumulator.

When the destination is a directly addressed byte, this instruction will clear combinations of bits in any RAM location or hardware register. The mask byte determining the pattern of bits to be cleared would either be a constant contained in the instruction or a value computed in the Accumulator at run-time. The instruction,

ANL P1, #01110011B

will clear bits 7, 3, and 2 of output port 1.

**Operation:**

ANL

 $(C) \leftarrow (C) \wedge \neg (\text{bit})$

**CJNE <dest-byte>, <src-byte>, rel**

**Function:** Compare and Jump if Not Equal.

**Description:** CJNE compares the magnitudes of the first two operands, and branches if their values are not equal. The branch destination is computed by adding the signed relative-displacement in the last instruction byte to the PC, after incrementing the PC to the start of the next instruction. The carry flag is set if the unsigned integer value of <dest-byte> is less than the unsigned integer value of <src-byte>; otherwise, the carry is cleared. Neither operand is affected.

The first two operands allow four addressing mode combinations: the Accumulator may be compared with any directly addressed byte or immediate data, and any indirect RAM location or working register can be compared with an immediate constant.

**Example:** The Accumulator contains 34H. Register 7 contains 56H. The first instruction in the sequence,

```

                CJNE R7, #60H, NOT_EQ
;               ...      ; R7 = 60H.
NOT_EQ:        JC  REQ_LOW  ; IF R7 < 60H.
;               ...      ; R7 > 60H.

```

sets the carry flag and branches to the instruction at label NOT\_EQ. By testing the carry flag, this instruction determines whether R7 is greater or less than 60H.

If the data being presented to Port 1 is also 34H, then the instruction,

```
WAIT: CJNE A,P1,WAIT
```

clears the carry flag and continues with the next instruction in sequence, since the Accumulator does equal the data read from P1. (If some other value was being input on P1, the program will loop at this point until the P1 data changes to 34H.)

CPL  
(bit)  $\leftarrow \neg$  (bit)

---

**DA A****Function:** Decimal-adjust Accumulator for Addition**Description:** DA A adjusts the eight-bit value in the Accumulator resulting from the earlier addition of two variables (each in packed-BCD format), producing two four-bit digits. Any ADD or ADDC instruction may have been used to perform the addition.

If Accumulator bits 3-0 are greater than nine (xxxx1010-xxxx1111), or if the AC flag is one, six is added to the Accumulator producing the proper BCD digit in the low-order nibble. This internal addition would set the carry flag if a carry-out of the low-order four-bit field propagated through all high-order bits, but it would not clear the carry flag otherwise.

If the carry flag is now set, or if the four high-order bits now exceed nine (1010xxxx-111xxxx), these high-order bits are incremented by six, producing the proper BCD digit in the high-order nibble. Again, this would set the carry flag if there was a carry-out of the high-order bits, but wouldn't clear the carry. The carry flag thus indicates if the sum of the original two BCD variables is greater than 100, allowing multiple precision decimal addition. OV is not affected.

All of this occurs during the one instruction cycle. Essentially, this instruction performs the decimal conversion by adding 00H, 06H, 60H, or 66H to the Accumulator, depending on initial Accumulator and PSW conditions.

*Note:* DA A *cannot* simply convert a hexadecimal number in the Accumulator to BCD notation, nor does DA A apply to decimal subtraction.

**Example:** The Accumulator holds the value 56H (01010110B) representing the packed BCD digits of the decimal number 56. Register 3 contains the value 67H (01100111B) representing the packed BCD digits of the decimal number 67. The carry flag is set. The instruction sequence.

```
ADDC  A,R3
DA     A
```

will first perform a standard twos-complement binary addition, resulting in the value 0BEH (10111110) in the Accumulator. The carry and auxiliary carry flags will be cleared.

The Decimal Adjust instruction will then alter the Accumulator to the value 24H (00100100B), indicating the packed BCD digits of the decimal number 24, the low-order two digits of the decimal sum of 56, 67, and the carry-in. The carry flag will be set by the Decimal Adjust instruction, indicating that a decimal overflow occurred. The true sum 56, 67, and 1 is 124.

BCD variables can be incremented or decremented by adding 01H or 99H. If the Accumulator initially holds 30H (representing the digits of 30 decimal), then the instruction sequence,

```
ADD   A,#99H
DA     A
```

will leave the carry set and 29H in the Accumulator, since  $30 + 99 = 129$ . The low-order byte of the sum can be interpreted to mean  $30 - 1 = 29$ .

**Bytes:** 1

**Cycles:** 1

**Encoding:**

1	1	0	1
0	1	0	0

**Operation:** DA  
 -contents of Accumulator are BCD

**Operation:** DEC  
 $((Ri)) \leftarrow ((Ri)) - 1$ **DIV AB****Function:** Divide**Description:** DIV AB divides the unsigned eight-bit integer in the Accumulator by the unsigned eight-bit integer in register B. The Accumulator receives the integer part of the quotient; register B receives the integer remainder. The carry and OV flags will be cleared.*Exception:* if B had originally contained 00H, the values returned in the Accumulator and B-register will be undefined and the overflow flag will be set. The carry flag is cleared in any case.**Example:** The Accumulator contains 251 (0FBH or 11111011B) and B contains 18 (12H or 00010010B). The instruction,

DIV AB

will leave 13 in the Accumulator (0DH or 00001101B) and the value 17 (11H or 00010001B) in B, since  $251 = (13 \times 18) + 17$ . Carry and OV will both be cleared.**Bytes:** 1**Cycles:** 4**Encoding:**

1 0 0 0	0 1 0 0
---------	---------

**Operation:** DIV  
 $(A)_{15-8} \leftarrow (A)/(B)$   
 $(B)_{7-0}$

**DJNZ <byte>,<rel-addr>**

**Function:** Decrement and Jump if Not Zero

**Description:** DJNZ decrements the location indicated by 1, and branches to the address indicated by the second operand if the resulting value is not zero. An original value of 00H will underflow to 0FFH. No flags are affected. The branch destination would be computed by adding the signed relative-displacement value in the last instruction byte to the PC, after incrementing the PC to the first byte of the following instruction.

The location decremented may be a register or directly addressed byte.

*Note:* When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.

**Example:** Internal RAM locations 40H, 50H, and 60H contain the values 01H, 70H, and 15H, respectively. The instruction sequence,

```
DJNZ 40H,LABEL__1
DJNZ 50H,LABEL__2
DJNZ 60H,LABEL__3
```

will cause a jump to the instruction at label LABEL\_\_2 with the values 00H, 6FH, and 15H in the three RAM locations. The first jump was *not* taken because the result was zero.

This instruction provides a simple way of executing a program loop a given number of times, or for adding a moderate time delay (from 2 to 512 machine cycles) with a single instruction. The instruction sequence,

```

                MOV     R2,#8
TOGGLE:        CPL     P1.7
                DJNZ    R2,TOGGLE
```

will toggle P1.7 eight times, causing four output pulses to appear at bit 7 of output Port 1. Each pulse will last three machine cycles; two for DJNZ and one to alter the pin.

**Operation:** JBC  
 $(PC) \leftarrow (PC) + 3$   
 IF (bit) = 1  
   THEN  
      $(bit) \leftarrow 0$   
      $(PC) \leftarrow (PC) + rel$

---

## JC rel

---

**Function:** Jump if Carry is set

**Description:** If the carry flag is set, branch to the address indicated; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative-displacement in the second instruction byte to the PC, after incrementing the PC twice. No flags are affected.

**Example:** The carry flag is cleared. The instruction sequence,

```
JC LABEL1
CPL C
JC LABEL2
```

will set the carry and cause program execution to continue at the instruction identified by the label LABEL2.

**Bytes:** 2

**Cycles:** 2

**Encoding:**

0 1 0 0	0 0 0 0
---------	---------

rel. address
--------------

**Operation:** JC  
 $(PC) \leftarrow (PC) + 2$   
 IF (C) = 1  
   THEN  
      $(PC) \leftarrow (PC) + rel$

**JMP @A + DPTR****Function:** Jump indirect**Description:** Add the eight-bit unsigned contents of the Accumulator with the sixteen-bit data pointer, and load the resulting sum to the program counter. This will be the address for subsequent instruction fetches. Sixteen-bit addition is performed (modulo  $2^{16}$ ): a carry-out from the low-order eight bits propagates through the higher-order bits. Neither the Accumulator nor the Data Pointer is altered. No flags are affected.**Example:** An even number from 0 to 6 is in the Accumulator. The following sequence of instructions will branch to one of four AJMP instructions in a jump table starting at JMP\_\_TBL:

```

                MOV    DPTR, #JMP__TBL
                JMP    @A + DPTR
JMP__TBL:      AJMP   LABEL0
                AJMP   LABEL1
                AJMP   LABEL2
                AJMP   LABEL3

```

If the Accumulator equals 04H when starting this sequence, execution will jump to label LABEL2. Remember that AJMP is a two-byte instruction, so the jump instructions start at every other address.

**Bytes:** 1**Cycles:** 2**Encoding:**

---	---	---	---	---	---	---	---

**Operation:**

JMP  
 $(PC) \leftarrow (A) + (DPTR)$

**JNB bit,rel**

**Function:** Jump if Bit Not set

**Description:** If the indicated bit is a zero, branch to the indicated address; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative-displacement in the third instruction byte to the PC, after incrementing the PC to the first byte of the next instruction. *The bit tested is not modified.* No flags are affected.

**Example:** The data present at input port 1 is 11001010B. The Accumulator holds 56H (01010110B). The instruction sequence,

```
JNB P1.3,LABEL1
JNB ACC.3,LABEL2
```

will cause program execution to continue at the instruction at label LABEL2.

**Bytes:** 3

**Cycles:** 2

     THEN  $(PC) \leftarrow (PC) + rel$

**JNZ rel**

**Function:** Jump if Accumulator Not Zero

**Description:** If any bit of the Accumulator is a one, branch to the indicated address; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative-displacement in the second instruction byte to the PC, after incrementing the PC twice. The Accumulator is not modified. No flags are affected.

**Example:** The Accumulator originally holds 00H. The instruction sequence,

```
JNZ LABEL1
INC A
JNZ LABEL2
```

will set the Accumulator to 01H and continue at label LABEL2.

**Bytes:** 2

**Cycles:** 2

**Encoding:**

rel. address
--------------

**Operation:** JNZ  
 $(PC) \leftarrow (PC) + 2$   
 IF  $(A) \neq 0$   
 THEN  $(PC) \leftarrow (PC) + rel$

**JZ rel**

**Function:** Jump if Accumulator Zero

**Description:** If all bits of the Accumulator are zero, branch to the address indicated; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative-displacement in the second instruction byte to the PC, after incrementing the PC twice. The Accumulator is not modified. No flags are affected.

**Example:** The Accumulator originally contains 01H. The instruction sequence,

```
JZ LABEL1
DEC A
JZ LABEL2
```

will change the Accumulator to 00H and cause program execution to continue at the instruction identified by the label LABEL2.

**Bytes:** 2

**Cycles:** 2

rel. address
--------------

**Operation:** JZ  
 $(PC) \leftarrow (PC) + 2$   
 IF  $(A) = 0$   
 THEN  $(PC) \leftarrow (PC) + rel$

**LCALL addr16****Function:** Long call

**Description:** LCALL calls a subroutine located at the indicated address. The instruction adds three to the program counter to generate the address of the next instruction and then pushes the 16-bit result onto the stack (low byte first), incrementing the Stack Pointer by two. The high-order and low-order bytes of the PC are then loaded, respectively, with the second and third bytes of the LCALL instruction. Program execution continues with the instruction at this address. The subroutine may therefore begin anywhere in the full 64K-byte program memory address space. No flags are affected.

**Example:** Initially the Stack Pointer equals 07H. The label "SUBRTN" is assigned to program memory location 1234H. After executing the instruction,

LCALL SUBRTN

at location 0123H, the Stack Pointer will contain 09H, internal RAM locations 08H and 09H will contain 26H and 01H, and the PC will contain 1234H.

**Bytes:** 3**Cycles:** 2**Encoding:**

0 0 0 1 0 0 1 0

addr15-addr8

addr7-addr0

**Operation:**

LCALL  
 $(PC) \leftarrow (PC) + 3$   
 $(SP) \leftarrow (SP) + 1$   
 $((SP)) \leftarrow (PC_{7-0})$   
 $(SP) \leftarrow (SP) + 1$   
 $((SP)) \leftarrow (PC_{15-8})$   
 $(PC) \leftarrow \text{addr}_{15-0}$

**LJMP addr16****Function:** Long Jump

**Description:** LJMP causes an unconditional branch to the indicated address, by loading the high-order and low-order bytes of the PC (respectively) with the second and third instruction bytes. The destination may therefore be anywhere in the full 64K program memory address space. No flags are affected.

**Example:** The label "JMPADR" is assigned to the instruction at program memory location 1234H. The instruction,

LJMP JMPADR

at location 0123H will load the program counter with 1234H.

**Bytes:** 3**Cycles:** 2**Encoding:**

0 0 0 0 0 0 1 0

addr15-addr8

addr7-addr0

**Operation:**

LJMP  
 $(PC) \leftarrow \text{addr}_{15-0}$

**MOV <dest-byte>,<src-byte>****Function:** Move byte variable**Description:** The byte variable indicated by the second operand is copied into the location specified by the first operand. The source byte is not affected. No other register or flag is affected.

This is by far the most flexible operation. Fifteen combinations of source and destination addressing modes are allowed.

**Example:** Internal RAM location 30H holds 40H. The value of RAM location 40H is 10H. The data present at input port 1 is 11001010B (0CAH).

```

MOV  R0,#30H  ;R0 <= 30H
MOV  A,@R0    ;A <= 40H
MOV  R1,A     ;R1 <= 40H
MOV  B,@R1    ;B <= 10H
MOV  @R1,P1   ;RAM (40H) <= 0CAH
MOV  P2,P1    ;P2 #0CAH

```

leaves the value 30H in register 0, 40H in both the Accumulator and register 1, 10H in register B, and 0CAH (11001010B) both in RAM location 40H and output on port 2.

**Operation:** MOV  
(DPTR) ← #data<sub>15-0</sub>  
DPH □ DPL ← #data<sub>15-8</sub> □ #data<sub>7-0</sub>

**MOVC A,@A+ <base-reg>****Function:** Move Code byte

**Description:** The MOVC instructions load the Accumulator with a code byte, or constant from program memory. The address of the byte fetched is the sum of the original unsigned eight-bit Accumulator contents and the contents of a sixteen-bit base register, which may be either the Data Pointer or the PC. In the latter case, the PC is incremented to the address of the following instruction before being added with the Accumulator; otherwise the base register is not altered. Sixteen-bit addition is performed so a carry-out from the low-order eight bits may propagate through higher-order bits. No flags are affected.

**Example:** A value between 0 and 3 is in the Accumulator. The following instructions will translate the value in the Accumulator to one of four values defined by the DB (define byte) directive.

```
REL_PC: INC    A
          MOVC  A,@A+PC
          RET
          DB    66H
          DB    77H
          DB    88H
          DB    99H
```

If the subroutine is called with the Accumulator equal to 01H, it will return with 77H in the Accumulator. The INC A before the MOVC instruction is needed to "get around" the RET instruction above the table. If several bytes of code separated the MOVC from the table, the corresponding number would be added to the Accumulator instead.

**MOVC A,@A+DPTR****Bytes:** 1**Cycles:** 2**Encoding:**

---------	---------

**Operation:** MOVC  
 $(PC) \leftarrow (PC) + 1$   
 $(A) \leftarrow ((A) + (PC))$

**MOVX <dest-byte>,<src-byte>**

---

**Function:** Move External**Description:** The MOVX instructions transfer data between the Accumulator and a byte of external data memory, hence the "X" appended to MOV. There are two types of instructions, differing in whether they provide an eight-bit or sixteen-bit indirect address to the external data RAM.

In the first type, the contents of R0 or R1 in the current register bank provide an eight-bit address multiplexed with data on P0. Eight bits are sufficient for external I/O expansion decoding or for a relatively small RAM array. For somewhat larger arrays, any output port pins can be used to output higher-order address bits. These pins would be controlled by an output instruction preceding the MOVX.

In the second type of MOVX instruction, the Data Pointer generates a sixteen-bit address. P2 outputs the high-order eight address bits (the contents of DPH) while P0 multiplexes the low-order eight bits (DPL) with data. The P2 Special Function Register retains its previous contents while the P2 output buffers are emitting the contents of DPH. This form is faster and more efficient when accessing very large data arrays (up to 64K bytes), since no additional instructions are needed to set up the output ports.

It is possible in some situations to mix the two MOVX types. A large RAM array with its high-order address lines driven by P2 can be addressed via the Data Pointer, or with code to output high-order address bits to P2 followed by a MOVX instruction using R0 or R1.

**Example:** An external 256 byte RAM using multiplexed address/data lines (e.g., an Intel 8155 RAM/I/O/Timer) is connected to the 8051 Port 0. Port 3 provides control lines for the external RAM. Ports 1 and 2 are used for normal I/O. Registers 0 and 1 contain 12H and 34H. Location 34H of the external RAM holds the value 56H. The instruction sequence,

```
MOVX A,@R1
```

```
MOVX @R0,A
```

copies the value 56H into both the Accumulator and external RAM location 12H.

**MOVX A,@Ri****Bytes:** 1**Cycles:** 2**Encoding:**

**Operation:** MOVX  
(DPTR) ← (A)

---

**MUL AB**

---

**Function:** Multiply**Description:** MUL AB multiplies the unsigned eight-bit integers in the Accumulator and register B. The low-order byte of the sixteen-bit product is left in the Accumulator, and the high-order byte in B. If the product is greater than 255 (0FFH) the overflow flag is set; otherwise it is cleared. The carry flag is always cleared.**Example:** Originally the Accumulator holds the value 80 (50H). Register B holds the value 160 (0A0H). The instruction,

MUL AB

will give the product 12,800 (3200H), so B is changed to 32H (00110010B) and the Accumulator is cleared. The overflow flag is set, carry is cleared.

**Bytes:** 1**Cycles:** 4**Encoding:**

1	0	1	0
---	---	---	---

---	---	---	---

**Operation:** NOP  
 $(PC) \leftarrow (PC) + 1$

**ORL** <dest-byte> <src-byte>

**Function:** Logical-OR for byte variables

**Description:** ORL performs the bitwise logical-OR operation between the indicated variables, storing the results in the destination byte. No flags are affected.

The two operands allow six addressing mode combinations. When the destination is the Accumulator, the source can use register, direct, register-indirect, or immediate addressing; when the destination is a direct address, the source can be the Accumulator or immediate data.

*Note:* When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.

**Example:** If the Accumulator holds 0C3H (11000011B) and R0 holds 55H (01010101B) then the instruction,

```
ORL A,R0
```

will leave the Accumulator holding the value 0D7H (11010111B).

When the destination is a directly addressed byte, the instruction can set combinations of bits in any RAM location or hardware register. The pattern of bits to be set is determined by a mask byte, which may be either a constant data value in the instruction or a variable computed in the Accumulator at run-time. The instruction,

```
ORL P1,#00110010B
```

will set bits 5, 4, and 1 of output Port 1.

**Operation:** ORL  
 $(C) \leftarrow (C) \vee (\overline{\text{bit}})$

**POP direct**

**Function:** Pop from stack.

**Description:** The contents of the internal RAM location addressed by the Stack Pointer is read, and the Stack Pointer is decremented by one. The value read is then transferred to the directly addressed byte indicated. No flags are affected.

**Example:** The Stack Pointer originally contains the value 32H, and internal RAM locations 30H through 32H contain the values 20H, 23H, and 01H, respectively. The instruction sequence,

POP DPH

POP DPL

will leave the Stack Pointer equal to the value 30H and the Data Pointer set to 0123H. At this point the instruction,

POP SP

will leave the Stack Pointer set to 20H. Note that in this special case the Stack Pointer was decremented to 2FH before being loaded with the value popped (20H).

**Bytes:** 2

**Cycles:** 2

**Encoding:**

----------------

**Operation:** PUSH  
 $(\text{SP}) \leftarrow (\text{SP}) + 1$   
 $((\text{SP})) \leftarrow (\text{direct})$

---

**RET**

---

**Function:** Return from subroutine**Description:** RET pops the high- and low-order bytes of the PC successively from the stack, decrementing the Stack Pointer by two. Program execution continues at the resulting address, generally the instruction immediately following an ACALL or LCALL. No flags are affected.**Example:** The Stack Pointer originally contains the value 0BH. Internal RAM locations 0AH and 0BH contain the values 23H and 01H, respectively. The instruction,

RET

will leave the Stack Pointer equal to the value 09H. Program execution will continue at location 0123H.

**Bytes:** 1**Cycles:** 2**Encoding:**

0	0	1	0	0	0	1	0
---	---	---	---	---	---	---	---

**Operation:**

```

RET
(PC15-8) ← ((SP))
(SP) ← (SP) - 1
(PC7-0) ← ((SP))
(SP) ← (SP) - 1

```

---

**RETI**

---

**Function:** Return from interrupt**Description:** RETI pops the high- and low-order bytes of the PC successively from the stack, and restores the interrupt logic to accept additional interrupts at the same priority level as the one just processed. The Stack Pointer is left decremented by two. No other registers are affected; the PSW is *not* automatically restored to its pre-interrupt status. Program execution continues at the resulting address, which is generally the instruction immediately after the point at which the interrupt request was detected. If a lower- or same-level interrupt had been pending when the RETI instruction is executed, that one instruction will be executed before the pending interrupt is processed.**Example:** The Stack Pointer originally contains the value 0BH. An interrupt was detected during the instruction ending at location 0122H. Internal RAM locations 0AH and 0BH contain the values 23H and 01H, respectively. The instruction,

RETI

will leave the Stack Pointer equal to 09H and return program execution to location 0123H.

**Bytes:** 1**Cycles:** 2**Encoding:**

0	0	1	1	0	0	1	0
---	---	---	---	---	---	---	---

**Operation:**

```

RETI
(PC15-8) ← ((SP))
(SP) ← (SP) - 1
(PC7-0) ← ((SP))
(SP) ← (SP) - 1

```

**RL A****Function:** Rotate Accumulator Left**Description:** The eight bits in the Accumulator are rotated one bit to the left. Bit 7 is rotated into the bit 0 position. No flags are affected.**Example:** The Accumulator holds the value 0C5H (11000101B). The instruction,

RL A

leaves the Accumulator holding the value 8BH (10001011B) with the carry unaffected.

**Bytes:** 1**Cycles:** 1**Encoding:**

0	0	1	0
---	---	---	---

0	0	1	1
---	---	---	---

**Operation:** RL  
 $(A_n + 1) \leftarrow (A_n) \quad n = 0 - 6$   
 $(A0) \leftarrow (A7)$ **RLC A****Function:** Rotate Accumulator Left through the Carry flag**Description:** The eight bits in the Accumulator and the carry flag are together rotated one bit to the left. Bit 7 moves into the carry flag; the original state of the carry flag moves into the bit 0 position. No other flags are affected.**Example:** The Accumulator holds the value 0C5H (11000101B), and the carry is zero. The instruction,

RLC A

leaves the Accumulator holding the value 8BH (10001010B) with the carry set.

**Bytes:** 1**Cycles:** 1**Encoding:**

0	0	1	1
---	---	---	---

0	0	1	1
---	---	---	---

**Operation:** RLC  
 $(A_n + 1) \leftarrow (A_n) \quad n = 0 - 6$   
 $(A0) \leftarrow (C)$   
 $(C) \leftarrow (A7)$

**RR A**

**Function:** Rotate Accumulator Right

**Description:** The eight bits in the Accumulator are rotated one bit to the right. Bit 0 is rotated into the bit 7 position. No flags are affected.

**Example:** The Accumulator holds the value 0C5H (11000101B). The instruction,

RR A

leaves the Accumulator holding the value 0E2H (11100010B) with the carry unaffected.

**Bytes:** 1

**Cycles:** 1

**Encoding:**

0 0 0 0	0 0 1 1
---------	---------

**Operation:** RR  
 $(A_n) \leftarrow (A_n + 1) \quad n = 0 - 6$   
 $(A7) \leftarrow (A0)$

**RRC A**

**Function:** Rotate Accumulator Right through Carry flag

**Description:** The eight bits in the Accumulator and the carry flag are together rotated one bit to the right. Bit 0 moves into the carry flag; the original value of the carry flag moves into the bit 7 position. No other flags are affected.

**Example:** The Accumulator holds the value 0C5H (11000101B), the carry is zero. The instruction,

RRC A

leaves the Accumulator holding the value 62 (01100010B) with the carry set.

**Bytes:** 1

**Cycles:** 1

**Encoding:**

0 0 0 1	0 0 1 1
---------	---------

**Operation:** RRC  
 $(A_n) \leftarrow (A_n + 1) \quad n = 0 - 6$   
 $(A7) \leftarrow (C)$   
 $(C) \leftarrow (A0)$

**SETB <bit>****Function:** Set Bit**Description:** SETB sets the indicated bit to one. SETB can operate on the carry flag or any directly addressable bit. No other flags are affected.**Example:** The carry flag is cleared. Output Port 1 has been written with the value 34H (00110100B). The instructions,

SETB C

SETB P1.0

will leave the carry flag set to 1 and change the data output on Port 1 to 35H (00110101B).

**SETB C****Bytes:** 1**Cycles:** 1**Encoding:**

1	1	0	1
---	---	---	---

---	---	---	---

bit address
-------------

**Operation:** SETB  
(bit) ← 1

**SJMP rel**

---

**Function:** Short Jump**Description:** Program control branches unconditionally to the address indicated. The branch destination is computed by adding the signed displacement in the second instruction byte to the PC, after incrementing the PC twice. Therefore, the range of destinations allowed is from 128 bytes preceding this instruction to 127 bytes following it.**Example:** The label "RELADR" is assigned to an instruction at program memory location 0123H. The instruction,**SJMP RELADR**

will assemble into location 0100H. After the instruction is executed, the PC will contain the value 0123H.

*(Note: Under the above conditions the instruction following SJMP will be at 102H. Therefore, the displacement byte of the instruction will be the relative offset (0123H-0102H) = 21H. Put another way, an SJMP with a displacement of 0FEH would be a one-instruction infinite loop.)***Bytes:** 2**Cycles:** 2**Encoding:**

1	0	0	0	0	0	0	0
---	---	---	---	---	---	---	---

rel. address
--------------

**Operation:** **SJMP**  
 $(PC) \leftarrow (PC) + 2$   
 $(PC) \leftarrow (PC) + \text{rel}$

**SUBB A,<src-byte>****Function:** Subtract with borrow

**Description:** SUBB subtracts the indicated variable and the carry flag together from the Accumulator, leaving the result in the Accumulator. SUBB sets the carry (borrow) flag if a borrow is needed for bit 7, and clears C otherwise. (If C was set *before* executing a SUBB instruction, this indicates that a borrow was needed for the previous step in a multiple precision subtraction, so the carry is subtracted from the Accumulator along with the source operand.) AC is set if a borrow is needed for bit 3, and cleared otherwise. OV is set if a borrow is needed into bit 6, but not into bit 7, or into bit 7, but not bit 6.

When subtracting signed integers OV indicates a negative number produced when a negative value is subtracted from a positive value, or a positive result when a positive number is subtracted from a negative number.

The source operand allows four addressing modes: register, direct, register-indirect, or immediate.

**Example:** The Accumulator holds 0C9H (11001001B), register 2 holds 54H (01010100B), and the carry flag is set. The instruction,

SUBB A,R2

will leave the value 74H (01110100B) in the accumulator, with the carry flag and AC cleared but OV set.

Notice that 0C9H minus 54H is 75H. The difference between this and the above result is due to the carry (borrow) flag being set before the operation. If the state of the carry is not known before starting a single or multiple-precision subtraction, it should be explicitly cleared by a CLR C instruction.

**SUBB A,Rn****Bytes:** 1**Cycles:** 1**Encoding:**

----------------

**Operation:** SUBB  
 $(A) \leftarrow (A) - (C) - \#data$ 

---

**SWAP A**

---

**Function:** Swap nibbles within the Accumulator**Description:** SWAP A interchanges the low- and high-order nibbles (four-bit fields) of the Accumulator (bits 3-0 and bits 7-4). The operation can also be thought of as a four-bit rotate instruction. No flags are affected.**Example:** The Accumulator holds the value 0C5H (11000101B). The instruction,

SWAP A

leaves the Accumulator holding the value 5CH (01011100B).

**Bytes:** 1**Cycles:** 1**Encoding:**

1 1 0 0	0 1 0 0
---------	---------

**Operation:** SWAP  
 $(A_{3-0}) \leftrightarrow (A_{7-4})$

**XCH A,<byte>**

**Function:** Exchange Accumulator with byte variable

**Description:** XCH loads the Accumulator with the contents of the indicated variable, at the same time writing the original Accumulator contents to the indicated variable. The source/destination operand can use register, direct, or register-indirect addressing.

**Example:** R0 contains the address 20H. The Accumulator holds the value 3FH (00111111B). Internal RAM location 20H holds the value 75H (01110101B). The instruction,

XCH A,@R0

will leave RAM location 20H holding the values 3FH (00111111B) and 75H (01110101B) in the accumulator.

**XCH A,Rn**

**Bytes:** 1

**Cycles:** 1

**Cycles:** 1

**Encoding:**

1	1	0	0
---	---	---	---

0	1	1	i
---	---	---	---

**Operation:** XCH  
(A)  $\leftrightarrow$  ((Ri))

**XCHD A,@RI****Function:** Exchange Digit**Description:** XCHD exchanges the low-order nibble of the Accumulator (bits 3-0), generally representing a hexadecimal or BCD digit, with that of the internal RAM location indirectly addressed by the specified register. The high-order nibbles (bits 7-4) of each register are not affected. No flags are affected.**Example:** R0 contains the address 20H. The Accumulator holds the value 36H (00110110B). Internal RAM location 20H holds the value 75H (01110101B). The instruction,

XCHD A,@R0

will leave RAM location 20H holding the value 76H (01110110B) and 35H (00110101B) in the Accumulator.

**Bytes:** 1**Cycles:** 1**Encoding:**

1	1	0	1	0	1	1	1
---	---	---	---	---	---	---	---

**Operation:** XCHD  
 $(A_{3:0}) \leftrightarrow ((Ri)_{3:0})$ **XRL <dest-byte>,<src-byte>****Function:** Logical Exclusive-OR for byte variables**Description:** XRL performs the bitwise logical Exclusive-OR operation between the indicated variables, storing the results in the destination. No flags are affected.

The two operands allow six addressing mode combinations. When the destination is the Accumulator, the source can use register, direct, register-indirect, or immediate addressing; when the destination is a direct address, the source can be the Accumulator or immediate data.

(Note: When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.)**Example:** If the Accumulator holds 0C3H (11000011B) and register 0 holds 0AAH (10101010B) then the instruction,

XRL A,R0

will leave the Accumulator holding the value 69H (01101001B).

When the destination is a directly addressed byte, this instruction can complement combinations of bits in any RAM location or hardware register. The pattern of bits to be complemented is then determined by a mask byte, either a constant contained in the instruction or a variable computed in the Accumulator at run-time. The instruction,

XRL P1,#00110001B

will complement bits 5, 4, and 0 of output Port 1.

# 8051, 8052 AND 80C51 HARDWARE DESCRIPTION

## INTRODUCTION

This chapter presents a comprehensive description of the on-chip hardware features of the MCS®-51 microcontrollers. Included in this description are

- The port drivers and how they function both as ports and, for Ports 0 and 2, in bus operations
- The Timer/Counters
- The Serial Interface
- The Interrupt System
- Reset
- The Reduced Power Modes in the CHMOS devices

- The EPROM versions of the 8051AH, 8052AH and 80C51BH

The devices under consideration are listed in Table 1. As it becomes unwieldy to be constantly referring to each of these devices by their individual names, we will adopt a convention of referring to them generically as 8051s and 8052s, unless a specific member of the group is being referred to, in which case it will be specifically named. The “8051s” include the 8051AH, 80C51BH, and their ROMless and EPROM versions. The “8052s” are the 8052AH, 8032AH and 8752BH.

Figure 1 shows a functional block diagram of the 8051s and 8052s.

**Table 1. The MCS-51 Family of Microcontrollers**

Device Name	ROMless Version	EPROM Version	ROM Bytes	RAM Bytes	16-bit Timers	Ckt Type
8051AH	8031AH	8751H, 8751BH	4K	128	2	HMOS
8052AH	8032AH	8752BH	8K	256	3	HMOS
80C51BH	80C31BH	87C51	4K	128	2	CHMOS

## Special Function Registers

A map of the on-chip memory area called SFR (Special Function Register) space is shown in Figure 2. SFRs marked by parentheses are resident in the 8052s but not in the 8051s.

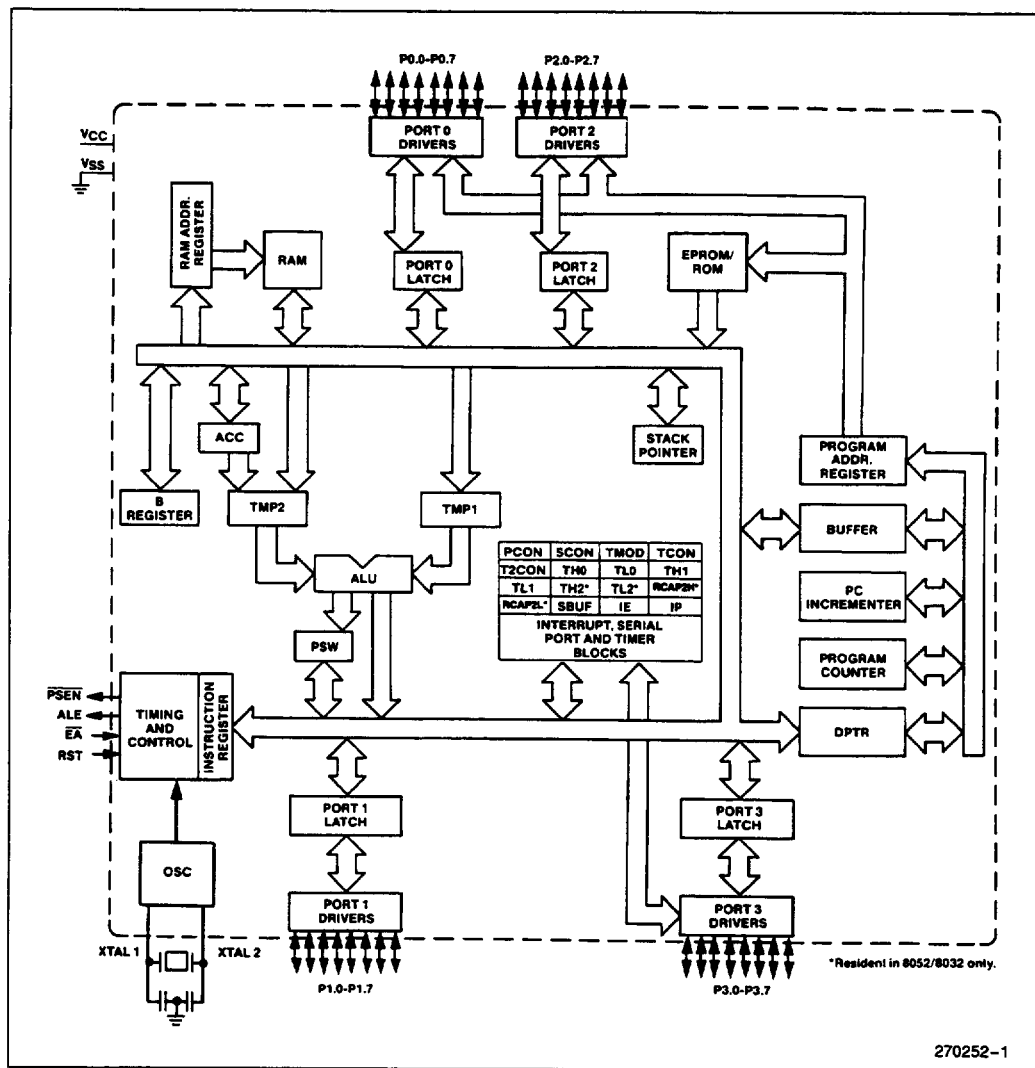

Figure 1. MCS-51 Architectural Block Diagram

80	P0	SP	DPL	DPH			PCON	87

Figure 2. SFR Map. ( . . . ) Indicates Resident in 8052s, not in 8051s

Note that not all of the addresses are occupied. Unoccupied addresses are not implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have no effect.

User software should not write 1s to these unimplemented locations, since they may be used in future MCS-51 products to invoke new features. In that case the reset or inactive values of the new bits will always be 0, and their active values will be 1.

The functions of the SFRs are outlined below.

### ACCUMULATOR

ACC is the Accumulator register. The mnemonics for Accumulator-Specific instructions, however, refer to the Accumulator simply as A.

### B REGISTER

The B register is used during multiply and divide operations. For other instructions it can be treated as another scratch pad register.

### PROGRAM STATUS WORD

The PSW register contains program status information as detailed in Figure 3.

### STACK POINTER

The Stack Pointer Register is 8 bits wide. It is incremented before data is stored during PUSH and CALL executions. While the stack may reside anywhere in on-chip RAM, the Stack Pointer is initialized to 07H after a reset. This causes the stack to begin at location 08H.

### DATA POINTER

The Data Pointer (DPTR) consists of a high byte (DPH) and a low byte (DPL). Its intended function is

to hold a 16-bit address. It may be manipulated as a 16-bit register or as two independent 8-bit registers.

### PORTS 0 TO 3

P0, P1, P2 and P3 are the SFR latches of Ports 0, 1, 2 and 3, respectively.

### SERIAL DATA BUFFER

The Serial Data Buffer is actually two separate registers, a transmit buffer and a receive buffer register. When data is moved to SBUF, it goes to the transmit buffer where it is held for serial transmission. (Moving a byte to SBUF is what initiates the transmission.) When data is moved from SBUF, it comes from the receive buffer.

### TIMER REGISTERS

Register pairs (TH0, TL0), (TH1, TL1), and (TH2, TL2) are the 16-bit Counting registers for Timer/Counters 0, 1, and 2, respectively.

### CAPTURE REGISTERS

The register pair (RCAP2H, RCAP2L) are the Capture registers for the Timer 2 "Capture Mode." In this mode, in response to a transition at the 8052's T2EX pin, TH2 and TL2 are copied into RCAP2H and RCAP2L. Timer 2 also has a 16-bit auto-reload mode, and RCAP2H and RCAP2L hold the reload value for this mode. More about Timer 2's features in a later section.

### CONTROL REGISTERS

Special Function Registers IP, IE, TMOD, TCON, T2CON, SCON, and PCON contain control and status bits for the interrupt system, the Timer/Counters, and the serial port. They are described in later sections.

(MSB)				(LSB)			
CY	AC	F0	RS1	RS0	OV	—	P

Symbol	Position	Name and Significance	Symbol	Position	Name and Significance
CY	PSW.7	Carry flag.	OV	PSW.2	Overflow flag.
AC	PSW.6	Auxiliary Carry flag. (For BCD operations.)	—	PSW.1	User definable flag.
F0	PSW.5	Flag 0 (Available to the user for general purposes.)	P	PSW.0	Parity flag.
RS1	PSW.4	Register bank select control bits 1 & 0. Set/cleared by software to determine working register bank (see Note).	NOTE: The contents of (RS1, RS0) enable the working register banks as follows:  (0.0)—Bank 0 (00H–07H) (0.1)—Bank 1 (08H–0FH) (1.0)—Bank 2 (10H–17H) (1.1)—Bank 3 (18H–1FH)		
RS0	PSW.3				

Figure 3. PSW: Program Status Word Register

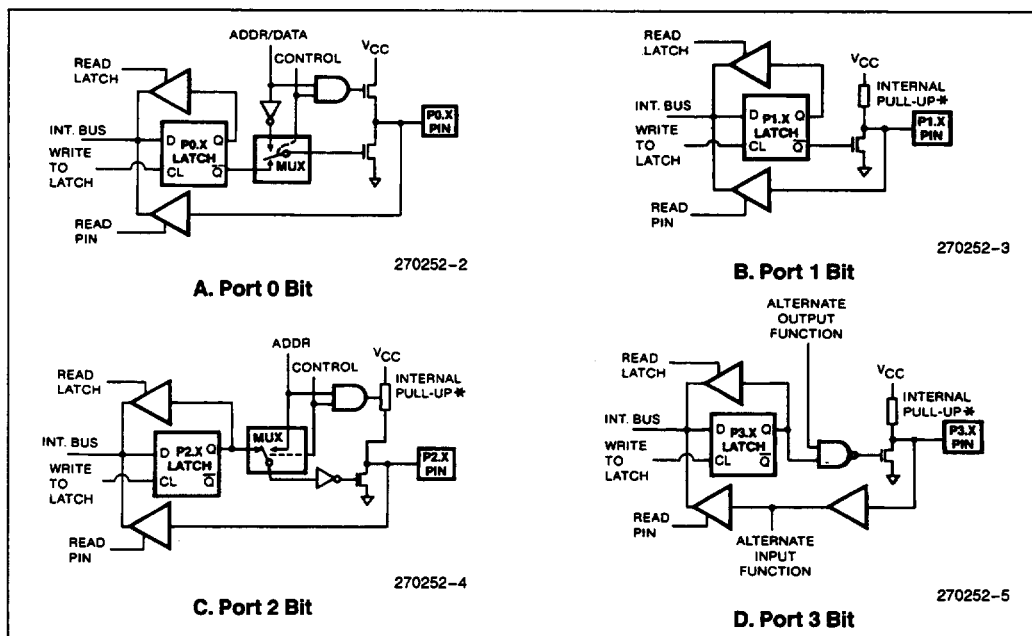

Figure 4. 8051 Port Bit Latches and I/O Buffers

\*See Figure 5 for details of the internal pullup.

## PORT STRUCTURES AND OPERATION

All four ports in the 8051 are bidirectional. Each consists of a latch (Special Function Registers P0 through P3), an output driver, and an input buffer.

The output drivers of Ports 0 and 2, and the input buffers of Port 0, are used in accesses to external memory. In this application, Port 0 outputs the low byte of the

external memory address, time-multiplexed with the byte being written or read. Port 2 outputs the high byte of the external memory address when the address is 16 bits wide. Otherwise the Port 2 pins continue to emit the P2 SFR content.

All the Port 3 pins, and (in the 8052) two Port 1 pins are multifunctional. They are not only port pins, but also serve the functions of various special features as listed on the following page.

Port Pin	Alternate Function
*P1.0	T2 (Timer/Counter 2 external input)
*P1.1	T2EX (Timer/Counter 2 Capture/Reload trigger)
P3.0	RXD (serial input port)
P3.1	TXD (serial output port)
P3.2	INT0 (external interrupt)
P3.3	INT1 (external interrupt)
P3.4	T0 (Timer/Counter 0 external input)
P3.5	T1 (Timer/Counter 1 external input)
P3.6	WR (external Data Memory write strobe)
P3.7	RD (external Data Memory read strobe)

\*P1.0 and P1.1 serve these alternate functions only on the 8052.

The alternate functions can only be activated if the corresponding bit latch in the port SFR contains a 1. Otherwise the port pin is stuck at 0.

## I/O Configurations

Figure 4 shows a functional diagram of a typical bit latch and I/O buffer in each of the four ports. The bit latch (one bit in the port's SFR) is represented as a Type D flip-flop, which will clock in a value from the internal bus in response to a "write to latch" signal from the CPU. The Q output of the flip-flop is placed on the internal bus in response to a "read latch" signal from the CPU. The level of the port pin itself is placed on the internal bus in response to a "read pin" signal from the CPU. Some instructions that read a port activate the "read latch" signal, and others activate the "read pin" signal. More about that later.

As shown in Figure 4, the output drivers of Ports 0 and 2 are switchable to an internal ADDR and ADDR/DATA bus by an internal CONTROL signal for use in external memory accesses. During external memory accesses, the P2 SFR remains unchanged, but the P0 SFR gets 1s written to it.

Also shown in Figure 4, is that if a P3 bit latch contains a 1, then the output level is controlled by the signal labeled "alternate output function." The actual P3.X pin level is always available to the pin's alternate input function, if any.

Ports 1, 2, and 3 have internal pullups. Port 0 has open drain outputs. Each I/O line can be independently used as an input or an output. (Ports 0 and 2 may not be used as general purpose I/O when being used as the

ADDR/DATA BUS). To be used as an input, the port bit latch must contain a 1, which turns off the output driver FET. Then, for Ports 1, 2, and 3, the pin is pulled high by the internal pullup, but can be pulled low by an external source.

Port 0 differs in not having internal pullups. The pullup FET in the P0 output driver (see Figure 4) is used only when the Port is emitting 1s during external memory accesses. Otherwise the pullup FET is off. Consequently P0 lines that are being used as output port lines are open drain. Writing a 1 to the bit latch leaves both output FETs off, so the pin floats. In that condition it can be used a high-impedance input.

Because Ports 1, 2, and 3 have fixed internal pullups they are sometimes called "quasi-bidirectional" ports. When configured as inputs they pull high and will source current (IIL, in the data sheets) when externally pulled low. Port 0, on the other hand, is considered "true" bidirectional, because when configured as an input it floats.

All the port latches in the 8051 have 1s written to them by the reset function. If a 0 is subsequently written to a port latch, it can be reconfigured as an input by writing a 1 to it.

## Writing to a Port

In the execution of an instruction that changes the value in a port latch, the new value arrives at the latch during S6P2 of the final cycle of the instruction. However, port latches are in fact sampled by their output buffers only during Phase 1 of any clock period. (During Phase 2 the output buffer holds the value it saw during the previous Phase 1). Consequently, the new value in the port latch won't actually appear at the output pin until the next Phase 1, which will be at S1P1 of the next machine cycle. See Figure 39 in the Internal Timing section.

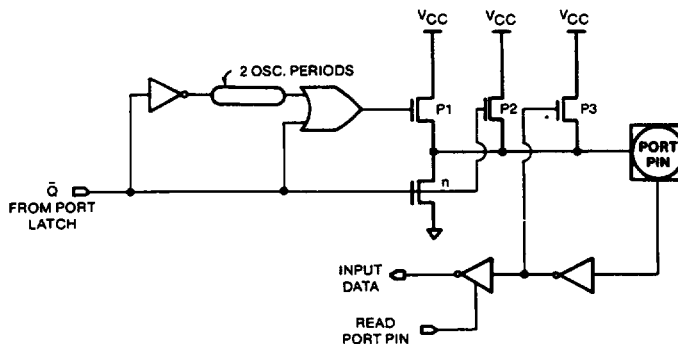

If the change requires a 0-to-1 transition in Port 1, 2, or 3, an additional pullup is turned on during S1P1 and S1P2 of the cycle in which the transition occurs. This is done to increase the transition speed. The extra pullup can source about 100 times the current that the normal pullup can. It should be noted that the internal pullups are field-effect transistors, not linear resistors. The pull-up arrangements are shown in Figure 5.

In HMOS versions of the 8051, the fixed part of the pullup is a depletion-mode transistor with the gate wired to the source. This transistor will allow the pin to source about 0.25 mA when shorted to ground. In parallel with the fixed pullup is an enhancement-mode transistor, which is activated during S1 whenever the port bit does a 0-to-1 transition. During this interval, if the port pin is shorted to ground, this extra transistor will allow the pin to source an additional 30 mA.

270252-6

**A. HMOS Configuration. The enhancement mode transistor is turned on for 2 osc. periods after  $\bar{Q}$  makes a 0-to-1 transition.**

270252-7

**B. CHMOS Configuration. pFET 1 is turned on for 2 osc. periods after  $\bar{Q}$  makes a 0-to-1 transition. During this time, pFET 1 also turns on pFET 3 through the inverter to form a latch which holds the 1. pFET 2 is also on.**

**Figure 5. Ports 1 And 3 HMOS And CHMOS Internal Pullup Configurations. Port 2 is Similar Except That It Holds The Strong Pullup On While Emitting 1s That Are Address Bits. (See Text, "Accessing External Memory").**

In the CHMOS versions, the pullup consists of three pFETs. It should be noted that an n-channel FET (nFET) is turned on when a logical 1 is applied to its gate, and is turned off when a logical 0 is applied to its gate. A p-channel FET (pFET) is the opposite: it is on when its gate sees a 0, and off when its gate sees a 1.

pFET1 in Figure 5 is the transistor that is turned on for 2 oscillator periods after a 0-to-1 transition in the port latch. While it's on, it turns on pFET3 (a weak pull-up), through the inverter. This inverter and pFET form a latch which hold the 1.

Note that if the pin is emitting a 1, a negative glitch on the pin from some external source can turn off pFET3, causing the pin to go into a float state. pFET2 is a very weak pullup which is on whenever the nFET is off, in traditional CMOS style. It's only about  $\frac{1}{10}$  the strength of pFET3. Its function is to restore a 1 to the pin in the event the pin had a 1 and lost it to a glitch.

## Port Loading and Interfacing

The output buffers of Ports 1, 2, and 3 can each drive 4 LS TTL inputs. These ports on HMOS versions can be driven in a normal manner by any TTL or NMOS circuit. Both HMOS and CHMOS pins can be driven by open-collector and open-drain outputs, but note that 0-to-1 transitions will not be fast. In the HMOS device, if the pin is driven by an open-collector output, a 0-to-1 transition will have to be driven by the relatively weak depletion mode FET in Figure 5(A). In the CHMOS device, an input 0 turns off pullup pFET3, leaving only the very weak pullup pFET2 to drive the transition.

In external bus mode, Port 0 output buffers can each drive 8 LS TTL inputs. As port pins, they require external pullups to drive any inputs.

## Read-Modify-Write Feature

Some instructions that read a port read the latch and others read the pin. Which ones do which? The instructions that read the latch rather than the pin are the ones that read a value, possibly change it, and then rewrite it to the latch. These are called "read-modify-write" instructions. The instructions listed below are read-modify-write instructions. When the destination operand is a port, or a port bit, these instructions read the latch rather than the pin:

ANL	(logical AND, e.g., ANL P1, A)
ORL	(logical OR, e.g., ORL P2, A)
XRL	(logical EX-OR, e.g., XRL P3, A)
JBC	(jump if bit = 1 and clear bit, e.g., JBC P1.1, LABEL)
CPL	(complement bit, e.g., CPL P3.0)
INC	(increment, e.g., INC P2)
DEC	(decrement, e.g., DEC P2)
DJNZ	(decrement and jump if not zero, e.g., DJNZ P3, LABEL)
MOV, PX.Y, C	(move carry bit to bit Y of Port X)
CLR PX.Y	(clear bit Y of Port X)
SETB PX.Y	(set bit Y of Port X)

It is not obvious that the last three instructions in this list are read-modify-write instructions, but they are. They read the port byte, all 8 bits, modify the addressed bit, then write the new byte back to the latch.

The reason that read-modify-write instructions are directed to the latch rather than the pin is to avoid a possible misinterpretation of the voltage level at the pin. For example, a port bit might be used to drive the base of a transistor. When a 1 is written to the bit, the transistor is turned on. If the CPU then reads the same port bit at the pin rather than the latch, it will read the base voltage of the transistor and interpret it as a 0. Reading the latch rather than the pin will return the correct value of 1.

## ACCESSING EXTERNAL MEMORY

Accesses to external memory are of two types: accesses to external Program Memory and accesses to external Data Memory. Accesses to external Program Memory use signal  $\overline{\text{PSEN}}$  (program store enable) as the read strobe. Accesses to external Data Memory use  $\overline{\text{RD}}$  or  $\overline{\text{WR}}$  (alternate functions of P3.7 and P3.6) to strobe the memory. Refer to Figures 36 through 38 in the Internal Timing section.

Fetches from external Program Memory always use a 16-bit address. Accesses to external Data Memory can use either a 16-bit address (MOVX @DPTR) or an 8-bit address (MOVX @Ri).

Whenever a 16-bit address is used, the high byte of the address comes out on Port 2, where it is held for the duration of the read or write cycle. Note that the Port 2 drivers use the strong pullups during the entire time that they are emitting address bits that are 1s. This is during the execution of a MOVX @DPTR instruction. During this time the Port 2 latch (the Special Function Register) does not have to contain 1s, and the contents of the Port 2 SFR are not modified. If the external memory cycle is not immediately followed by another external memory cycle, the undisturbed contents of the Port 2 SFR will reappear in the next cycle.

If an 8-bit address is being used (MOVX @Ri), the contents of the Port 2 SFR remain at the Port 2 pins throughout the external memory cycle. This will facilitate paging.

In any case, the low byte of the address is time-multiplexed with the data byte on Port 0. The ADDR/DATA signal drives both FETs in the Port 0 output buffers. Thus, in this application the Port 0 pins are not open-drain outputs, and do not require external pullups. Signal ALE (Address Latch Enable) should be used to capture the address byte into an external latch. The address byte is valid at the negative transition of ALE. Then, in a write cycle, the data byte to be written appears on Port 0 just before  $\overline{\text{WR}}$  is activated, and remains there until after  $\overline{\text{WR}}$  is deactivated. In a read cycle, the incoming byte is accepted at Port 0 just before the read strobe is deactivated.

During any access to external memory, the CPU writes 0FFH to the Port 0 latch (the Special Function Register), thus obliterating whatever information the Port 0 SFR may have been holding. If the user writes to Port 0 during an external memory fetch, the incoming code byte is corrupted. Therefore, do not write to Port 0 if external program memory is used.

External Program Memory is accessed under two conditions:

- 1) Whenever signal  $\overline{\text{EA}}$  is active; or
- 2) Whenever the program counter (PC) contains a number that is larger than 0FFFF (1FFFF for the 8052).

This requires that the ROMless versions have  $\overline{\text{EA}}$  wired low to enable the lower 4K (8K for the 8032) program bytes to be fetched from external memory.

When the CPU is executing out of external Program Memory, all 8 bits of Port 2 are dedicated to an output function and may not be used for general purpose I/O. During external program fetches they output the high byte of the PC. During this time the Port 2 drivers use the strong pullups to emit PC bits that are 1s.

## TIMER/COUNTERS

The 8051 has two 16-bit Timer/Counter registers: Timer 0 and Timer 1. The 8052 has these two plus one

more: Timer 2. All three can be configured to operate either as timers or event counters.

In the "Timer" function, the register is incremented every machine cycle. Thus, one can think of it as counting machine cycles. Since a machine cycle consists of 12 oscillator periods, the count rate is  $\frac{1}{12}$  of the oscillator frequency.

In the "Counter" function, the register is incremented in response to a 1-to-0 transition at its corresponding external input pin, T0, T1 or (in the 8052) T2. In this function, the external input is sampled during S5P2 of every machine cycle. When the samples show a high in one cycle and a low in the next cycle, the count is incremented. The new count value appears in the register during S3P1 of the cycle following the one in which the transition was detected. Since it takes 2 machine cycles (24 oscillator periods) to recognize a 1-to-0 transition, the maximum count rate is  $\frac{1}{24}$  of the oscillator frequency. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full machine cycle.

In addition to the "Timer" or "Counter" selection, Timer 0 and Timer 1 have four operating modes from which to select. Timer 2, in the 8052, has three modes of operation: "Capture," "Auto-Reload" and "baud rate generator."

## Timer 0 and Timer 1

These Timer/Counters are present in both the 8051 and the 8052. The "Timer" or "Counter" function is selected by control bits C/T in the Special Function Register TMOD (Figure 6). These two Timer/Counters have

four operating modes, which are selected by bit-pairs (M1, M0) in TMOD. Modes 0, 1, and 2 are the same for both Timer/Counters. Mode 3 is different. The four operating modes are described in the following text.

### MODE 0

Either Timer in Mode 0 is an 8-bit Counter with a divide-by-32 prescaler. This 13-bit timer is MCS-48 compatible. Figure 7 shows the Mode 0 operation as it applies to Timer 1.

In this mode, the Timer register is configured as a 13-Bit register. As the count rolls over from all 1s to all 0s, it sets the Timer interrupt flag TF1. The counted input is enabled to the Timer when TR1 = 1 and either GATE = 0 or INT1 = 1. (Setting GATE = 1 allows the Timer to be controlled by external input INT1, to facilitate pulse width measurements.) TR1 is a control bit in the Special Function Register TCON (Figure 8). GATE is in TMOD.

The 13-Bit register consists of all 8 bits of TH1 and the lower 5 bits of TL1. The upper 3 bits of TL1 are indeterminate and should be ignored. Setting the run flag (TR1) does not clear the registers.

Mode 0 operation is the same for Timer 0 as for Timer 1. Substitute TR0, TF0 and INT0 for the corresponding Timer 1 signals in Figure 7. There are two different GATE bits, one for Timer 1 (TMOD.7) and one for Timer 0 (TMOD.3).

### MODE 1

Mode 1 is the same as Mode 0, except that the Timer register is being run with all 16 bits.

(MSB)				(LSB)			
GATE	C/T	M1	M0	GATE	C/T	M1	M0
Timer 1				Timer 0			
GATE				M1	M0	Operating Mode	
				0	0	8-bit Timer/Counter "THx" with "TLx" as 5-bit prescaler.	
				0	1	16-bit Timer/Counter "THx" and "TLx" are cascaded; there is no prescaler.	
				1	0	8-bit auto-reload Timer/Counter "THx" holds a value which is to be reloaded into "TLx" each time it overflows.	
				1	1	(Timer 0) TLO is an 8-bit Timer/Counter controlled by the standard Timer 0 control bits. TH0 is an 8-bit timer only controlled by Timer 1 control bits.	
				1	1	(Timer 1) Timer/Counter 1 stopped.	

Gating control when set. Timer/Counter "x" is enabled only while "INTx" pin is high and "TRx" control pin is set. When cleared Timer "x" is enabled whenever "TRx" control bit is set.

Timer or Counter Selector cleared for Timer operation (input from internal system clock). Set for Counter operation (input from "Tx" input pin).

Figure 6. TMOD: Timer/Counter Mode Control Register

Figure 7. Timer/Counter 1 Mode 0: 13-Bit Counter

(MSB)				(LSB)			
TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0
Symbol	Position	Name and Significance		Symbol	Position	Name and Significance	
TF1	TCON.7	Timer 1 overflow Flag. Set by hardware on Timer/Counter overflow. Cleared by hardware when processor vectors to interrupt routine.		IE1	TCON.3	Interrupt 1 Edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed.	
TR1	TCON.6	Timer 1 Run control bit. Set/cleared by software to turn Timer/Counter on/off.		IT1	TCON.2	Interrupt 1 Type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts.	
TF0	TCON.5	Timer 0 overflow Flag. Set by hardware on Timer/Counter overflow. Cleared by hardware when processor vectors to interrupt routine.		IE0	TCON.1	Interrupt 0 Edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed.	
TR0	TCON.4	Timer 0 Run control bit. Set/cleared by software to turn Timer/Counter on/off.		IT0	TCON.0	Interrupt 0 Type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts.	

Figure 8.TCON: Timer/Counter Control Register

## MODE 2

Mode 2 configures the Timer register as an 8-bit Counter (TL1) with automatic reload, as shown in Figure 9. Overflow from TL1 not only sets TF1, but also reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged.

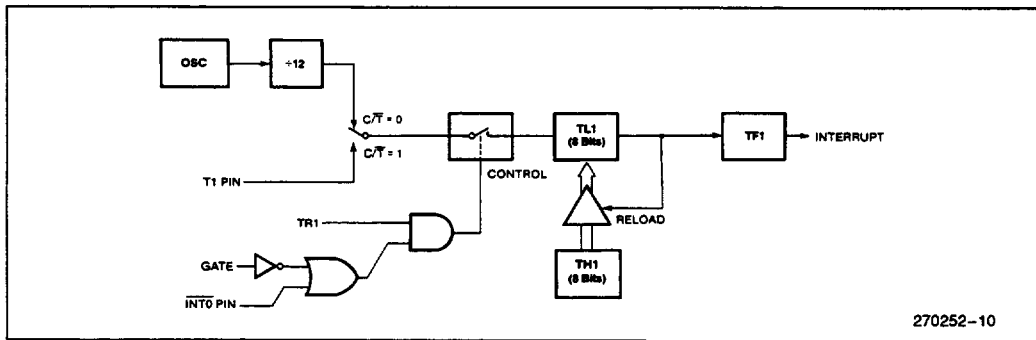

Mode 2 operation is the same for Timer/Counter 0.

## MODE 3

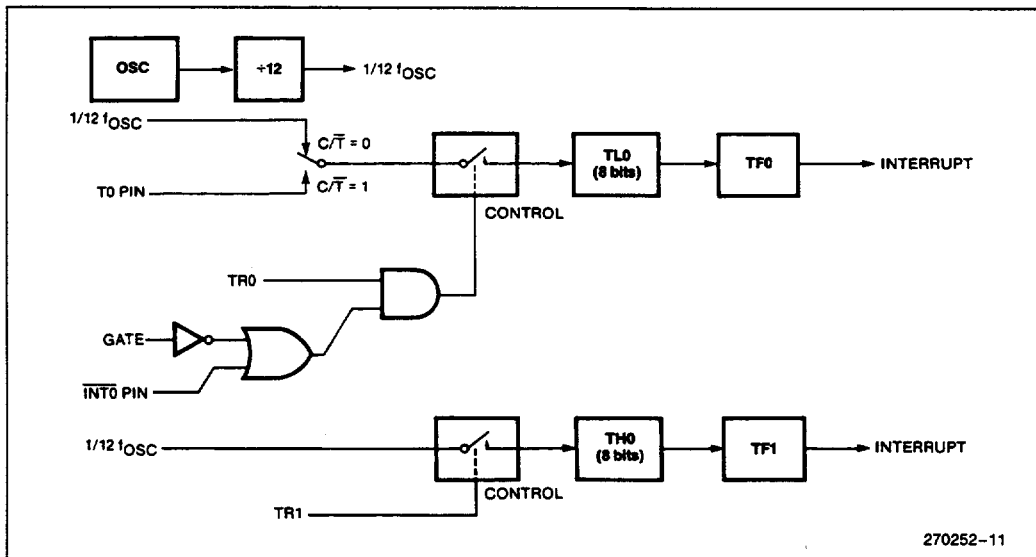

Timer 1 in Mode 3 simply holds its count. The effect is the same as setting TR1 = 0.

Timer 0 in Mode 3 establishes TL0 and TH0 as two separate counters. The logic for Mode 3 on Timer 0 is shown in Figure 10. TL0 uses the Timer 0 control bits: C/T, GATE, TR0, INT0, and TF0. TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now controls the "Timer 1" interrupt.

Mode 3 is provided for applications requiring an extra 8-bit timer or counter. With Timer 0 in Mode 3, an 8051 can look like it has three Timer/Counters, and an 8052, like it has four. When Timer 0 is in Mode 3, Timer 1 can be turned on and off by switching it out of and into its own Mode 3, or can still be used by the serial port as a baud rate generator, or in fact, in any application not requiring an interrupt.

### Figure 9. Timer/Counter 1 Mode 2: 8-Bit Auto-Reload

### Figure 10. Timer/Counter 0 Mode 3: Two 8-Bit Counters

## Timer 2

Timer 2 is a 16-bit Timer/Counter which is present only in the 8052. Like Timers 0 and 1, it can operate either as a timer or as an event counter. This is selected by bit C/T<sub>2</sub> in the Special Function Register T2CON (Figure 11). It has three operating modes: “capture,” “auto-load” and “baud rate generator,” which are selected by bits in T2CON as shown in Table 2.

### Table 2. Timer 2 Operating Modes

RCLK + TCLK	CP/RL2	TR2	Mode
0	0	1	16-bit Auto-Reload
0	1	1	16-bit Capture
1	X	1	Baud Rate Generator
X	X	0	(off)

(MSB)				(LSB)			
TF2	EXF2	RCLK	TCLK	EXEN2	TR2	C/T2	CP/RL2
Symbol	Position	Name and Significance					
TF2	T2CON.7	Timer 2 overflow flag set by a Timer 2 overflow and must be cleared by software. TF2 will not be set when either RCLK = 1 or TCLK = 1.					
EXF2	T2CON.6	Timer 2 external flag set when either a capture or reload is caused by a negative transition on T2EX and EXEN2 = 1. When Timer 2 interrupt is enabled, EXF2 = 1 will cause the CPU to vector to the Timer 2 interrupt routine. EXF2 must be cleared by software.					
RCLK	T2CON.5	Receive clock flag. When set, causes the serial port to use Timer 2 overflow pulses for its receive clock in Modes 1 and 3. RCLK = 0 causes Timer 1 overflow to be used for the receive clock.					
TCLK	T2CON.4	Transmit clock flag. When set, causes the serial port to use Timer 2 overflow pulses for its transmit clock in modes 1 and 3. TCLK = 0 causes Timer 1 overflows to be used for the transmit clock.					
EXEN2	T2CON.3	Timer 2 external enable flag. When set, allows a capture or reload to occur as a result of a negative transition on T2EX if Timer 2 is not being used to clock the serial port. EXEN2 = 0 causes Timer 2 to ignore events at T2EX.					
TR2	T2CON.2	Start/stop control for Timer 2. A logic 1 starts the timer.					
C/T2	T2CON.1	Timer or counter select. (Timer 2) 0 = Internal timer (OSC/12) 1 = External event counter (falling edge triggered).					
CP/RL2	T2CON.0	Capture/Reload flag. When set, captures will occur on negative transitions at T2EX if EXEN2 = 1. When cleared, auto-reloads will occur either with Timer 2 overflows or negative transitions at T2EX when EXEN2 = 1. When either RCLK = 1 or TCLK = 1, this bit is ignored and the timer is forced to auto-reload on Timer 2 overflow.					

Figure 11. T2CON: Timer/Counter 2 Control Register

In the Capture Mode there are two options which are selected by bit EXEN2 in T2CON. If EXEN2 = 0, then Timer 2 is a 16-bit timer or counter which upon overflowing sets bit TF2, the Timer 2 overflow bit, which can be used to generate an interrupt. If EXEN2 = 1, then Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX causes the current value in the Timer 2 registers, TL2 and TH2, to be captured into registers RCAP2L and RCAP2H, respectively. (RCAP2L and RCAP2H are new Special Function Registers in the 8052.) In addition, the transition at T2EX causes bit EXF2 in T2CON to be set, and EXF2, like TF2, can generate an interrupt.

The Capture Mode is illustrated in Figure 12.

In the auto-reload mode there are again two options, which are selected by bit EXEN2 in T2CON. If EXEN2 = 0, then when Timer 2 rolls over it not only sets TF2 but also causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2L and RCAP2H, which are preset by software. If EXEN2 = 1, then Timer 2 still does the above, but with the

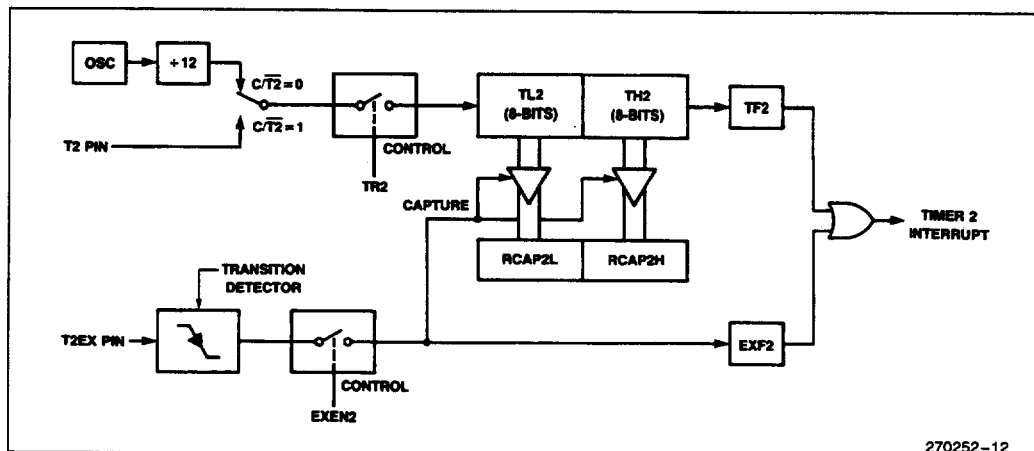

added feature that a 1-to-0 transition at external input T2EX will also trigger the 16-bit reload and set EXF2.

The auto-reload mode is illustrated in Figure 13.

The baud rate generator mode is selected by RCLK = 1 and/or TCLK = 1. It will be described in conjunction with the serial port.

## SERIAL INTERFACE

The serial port is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the receive register. (However, if the first byte still hasn't been read by the time reception of the second byte is complete, one of the bytes will be lost). The serial port receive and transmit registers are both accessed at Special Function Register SBUF. Writing to SBUF loads the transmit register, and reading SBUF accesses a physically separate receive register.

### Figure 12. Timer 2 in Capture Mode

**The serial port can operate in 4 modes:**

**Mode 0:** Serial data enters and exits through RXD. TXD outputs the shift clock. 8 bits are transmitted/received: 8 data bits (LSB first). The baud rate is fixed at 1/12 the oscillator frequency.

**Mode 1:** 10 bits are transmitted (through TXD) or received (through RXD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in Special Function Register SCON. The baud rate is variable.

**Mode 2:** 11 bits are transmitted (through TXD) or received (through RXD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On Transmit, the 9th data bit (TB8 in SCON) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in Special Function Register SCON, while the stop bit is ignored. The baud rate is programmable to either  $\frac{1}{32}$  or  $\frac{1}{64}$  the oscillator frequency.

**Mode 3:** 11 bits are transmitted (through TXD) or received (through RXD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except the baud rate. The baud rate in Mode 3 is variable.

In all four modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in Mode 0 by the condition  $RI = 0$  and  $REN = 1$ . Reception is initiated in the other modes by the incoming start bit if  $REN = 1$ .

## Multiprocessor Communications

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor systems is as follows.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With  $SM2 = 1$ , no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its  $SM2$  bit and prepare to receive the data bytes that will be coming. The slaves that weren't being addressed leave their  $SM2$ s set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. In a Mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

## Serial Port Control Register

The serial port control and status register is the Special Function Register SCON, shown in Figure 14. This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (TI and RI).

Figure 13. Timer 2 in Auto-Reload Mode

(MSB)				(LSB)			
SM0	SM1	SM2	REN	TB8	RB8	TI	RI

Where SM0, SM1 specify the serial port mode, as follows:

SM0	SM1	Mode	Description	Baud Rate
0	0	0	shift register	$f_{osc}/12$
0	1	1	8-bit UART	variable
1	0	2	9-bit UART	$f_{osc}/64$ or $f_{osc}/32$
1	1	3	9-bit UART variable	

- SM2 enables the multiprocessor communication feature in Modes 2 and 3. In Mode 2 or 3, if SM2 is set to 1 then RI will not be activated if the received 9th data bit (RB8) is 0. In Mode 1, if SM2 = 1 then RI will not be activated if a valid stop bit was not received. In Mode 0, SM2 should be 0.
- REN enables serial reception. Set by software to enable reception. Clear by software to disable reception.
- TB8 is the 9th data bit that will be transmitted in Modes 2 and 3. Set or clear by software as desired.
- RB8 in Modes 2 and 3, is the 9th data bit that was received. In Mode 1, if SM2 = 0, RB8 is the stop bit that was received. In Mode 0, RB8 is not used.
- TI is transmit interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or at the beginning of the stop bit in the other modes, in any serial transmission. Must be cleared by software.
- RI is receive interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or halfway through the stop bit time in the other modes, in any serial reception (except see SM2). Must be cleared by software.

Figure 14. SCON: Serial Port Control Register

## Baud Rates

The baud rate in Mode 0 is fixed:

$$\text{Mode 0 Baud Rate} = \frac{\text{Oscillator Frequency}}{12}$$

The baud rate in Mode 2 depends on the value of bit SMOD in Special Function Register PCON. If SMOD = 0 (which is the value on reset), the baud rate is  $\frac{1}{64}$  the oscillator frequency. If SMOD = 1, the baud rate is  $\frac{1}{32}$  the oscillator frequency.

$$\text{Mode 2 Baud Rate} = \frac{2^{\text{SMOD}}}{64} \times (\text{Oscillator Frequency})$$

In the 8051, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate. In the 8052, these baud rates can be determined by Timer 1, or by Timer 2, or by both (one for transmit and the other for receive).

### Using Timer 1 to Generate Baud Rates

When Timer 1 is used as the baud rate generator, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate and the value of SMOD as follows:

$$\text{Baud Rate} = \frac{2^{\text{SMOD}}}{32} \times (\text{Timer 1 Overflow Rate})$$

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either "timer" or "counter" operation, and in any of its 3 running modes. In the most typical applications, it is configured for "timer" operation, in the auto-reload

mode (high nibble of TMOD = 0010B). In that case, the baud rate is given by the formula

$$\text{Baud Rate} = \frac{2^{\text{SMOD}}}{32} \times \frac{\text{Oscillator Frequency}}{12 \times [256 - (\text{TH1})]}$$

One can achieve very low baud rates with Timer 1 by leaving the Timer 1 interrupt enabled, and configuring the Timer to run as a 16-bit timer (high nibble of TMOD = 0001B), and using the Timer 1 interrupt to do a 16-bit software reload.

Figure 15 lists various commonly used baud rates and how they can be obtained from Timer 1.

Baud Rate	fosc	SMOD	Timer 1		
			C/T	Mode	Reload Value
Mode 0 Max: 1 MHZ	12 MHZ	X	X	X	X
Mode 2 Max: 375K	12 MHZ	1	X	X	X
Modes 1, 3: 62.5K	12 MHZ	1	0	2	FFH
19.2K	11.059 MHZ	1	0	2	FDH
9.6K	11.059 MHZ	0	0	2	FDH
4.8K	11.059 MHZ	0	0	2	FAH
2.4K	11.059 MHZ	0	0	2	F4H
1.2K	11.059 MHZ	0	0	2	E8H
137.5	11.986 MHZ	0	0	2	1DH
110	6 MHZ	0	0	2	72H
110	12 MHZ	0	0	1	FEEDH

Figure 15. Timer 1 Generated Commonly Used Baud Rates

### Using Timer 2 to Generate Baud Rates

In the 8052, Timer 2 is selected as the baud rate generator by setting TCLK and/or RCLK in T2CON (Figure

11). Note then the baud rates for transmit and receive can be simultaneously different. Setting RCLK and/or TCLK puts Timer 2 into its baud rate generator mode, as shown in Figure 16.

Figure 16. Timer 2 in Baud Rate Generator Mode

The baud rate generator mode is similar to the auto-reload mode, in that a rollover in TH2 causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2H and RCAP2L, which are preset by software.

Now, the baud rates in Modes 1 and 3 are determined by Timer 2's overflow rate as follows:

$$\text{Modes 1, 3 Baud Rate} = \frac{\text{Timer 2 Overflow Rate}}{16}$$

The Timer can be configured for either "timer" or "counter" operation. In the most typical applications, it is configured for "timer" operation ( $C/T2 = 0$ ). "Timer" operation is a little different for Timer 2 when it's being used as a baud rate generator. Normally, as a timer it would increment every machine cycle (thus at  $1/2$  the oscillator frequency). As a baud rate generator, however, it increments every state time (thus at  $1/2$  the oscillator frequency). In that case the baud rate is given by the formula

$$\text{Modes 1, 3 Baud Rate} = \frac{\text{Oscillator Frequency}}{32x [65536 - (\text{RCAP2H}, \text{RCAP2L})]}$$

where (RCAP2H, RCAP2L) is the content of RCAP2H and RCAP2L taken as a 16-bit unsigned integer.

Timer 2 as a baud rate generator is shown in Figure 16. This Figure is valid only if  $\text{RCLK} + \text{TCLK} = 1$  in T2CON. Note that a rollover in TH2 does not set TF2, and will not generate an interrupt. Therefore, the Timer 2 interrupt does not have to be disabled when Timer 2 is in the baud rate generator mode. Note too, that if EXEN2 is set, a 1-to-0 transition in T2EX will set EXF2 but will not cause a reload from (RCAP2H, RCAP2L) to (TH2, TL2). Thus when Timer 2 is in use as a baud rate generator, T2EX can be used as an extra external interrupt, if desired.

It should be noted that when Timer 2 is running ( $\text{TR2} = 1$ ) in "timer" function in the baud rate generator mode, one should not try to read or write TH2 or TL2. Under these conditions the Timer is being incremented every state time, and the results of a read or write may not be accurate. The RCAP registers may be read, but shouldn't be written to, because a write might overlap a reload and cause write and/or reload errors. Turn the Timer off (clear TR2) before accessing the Timer 2 or RCAP registers, in this case.

## More About Mode 0

Serial data enters and exits through RXD. TXD outputs the shift clock. 8 bits are transmitted/received: 8 data bits (LSB first). The baud rate is fixed at  $1/12$  the oscillator frequency.

Figure 17 shows a simplified functional diagram of the serial port in Mode 0, and associated timing.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "write to SBUF" signal at S6P2 also loads a 1 into the 9th position of the transmit shift register and tells the TX Control block to commence a transmission. The internal timing is such that one full machine cycle will elapse between "write to SBUF," and activation of SEND.

SEND enables the output of the shift register to the alternate output function line of P3.0, and also enables SHIFT CLOCK to the alternate output function line of P3.1. SHIFT CLOCK is low during S3, S4, and S5 of every machine cycle, and high during S6, S1 and S2. At S6P2 of every machine cycle in which SEND is active, the contents of the transmit shift register are shifted to the right one position.

As data bits shift out to the right, zeroes come in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position, is just to the left of the MSB, and all positions to the left of that contain zeroes. This condition flags the TX Control block to do one last shift and then deactivate SEND and set TI. Both of these actions occur at S1P1 of the 10th machine cycle after "write to SBUF."

Reception is initiated by the condition  $\text{REN} = 1$  and  $\text{R1} = 0$ . At S6P2 of the next machine cycle, the RX Control unit writes the bits 11111110 to the receive shift register, and in the next clock phase activates RECEIVE.

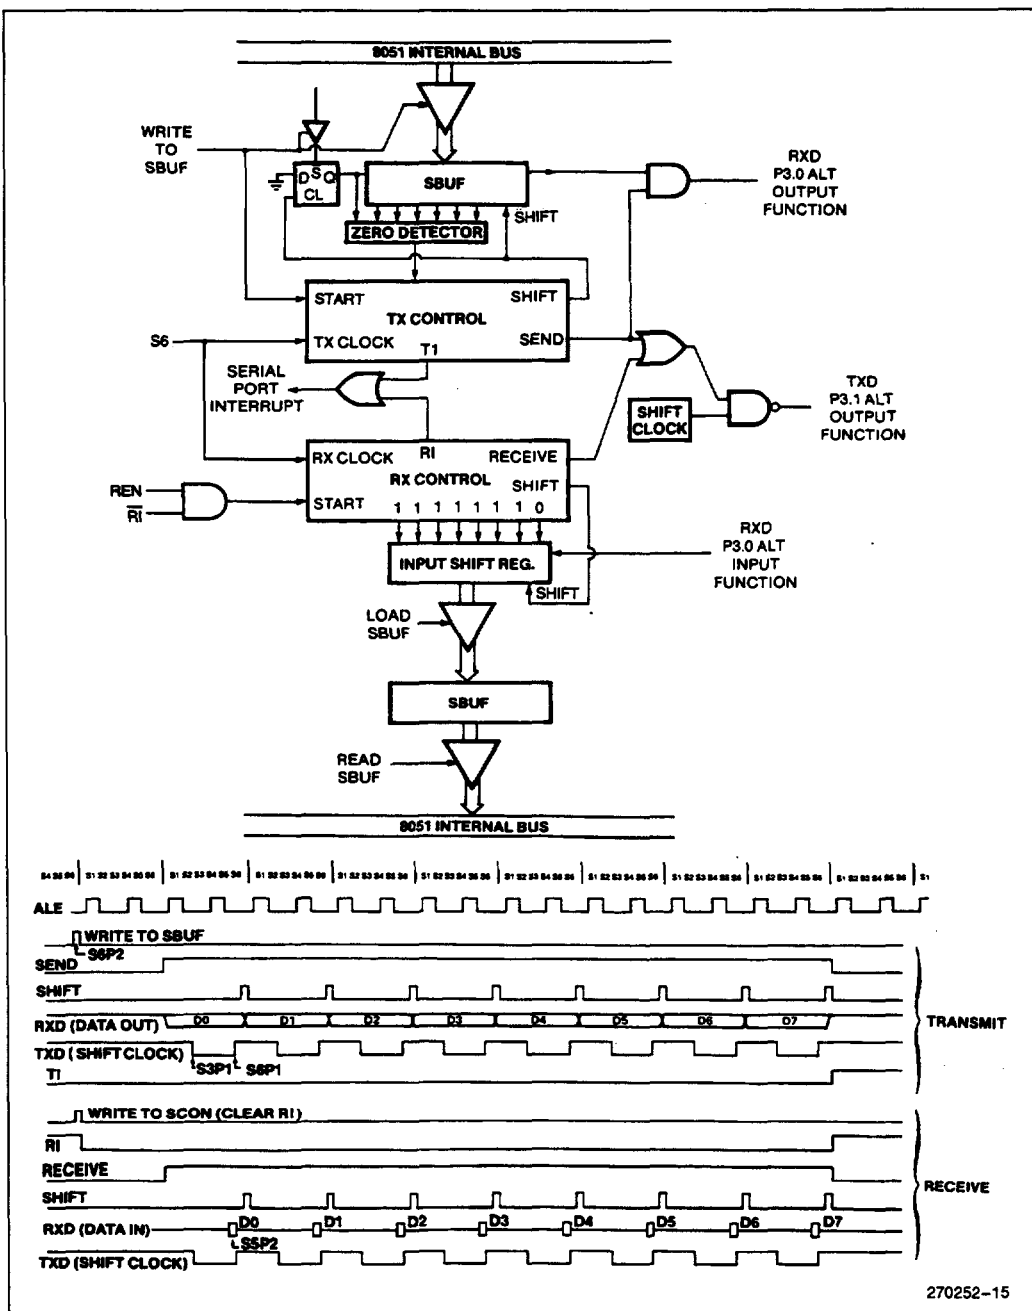

RECEIVE enables SHIFT CLOCK to the alternate output function line of P3.1. SHIFT CLOCK makes transitions at S3P1 and S6P1 of every machine cycle. At S6P2 of every machine cycle in which RECEIVE is active, the contents of the receive shift register are shifted to the left one position. The value that comes in from the right is the value that was sampled at the P3.0 pin at S5P2 of the same machine cycle.

As data bits come in from the right, 1s shift out to the left. When the 0 that was initially loaded into the rightmost position arrives at the leftmost position in the shift register, it flags the RX Control block to do one last shift and load SBUF. At S1P1 of the 10th machine cycle after the write to SCON that cleared RI, RECEIVE is cleared and RI is set.

## More About Mode 1

Ten bits are transmitted (through TXD), or received (through RXD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in SCON. In the 8051 the baud rate is determined by the Timer 1 overflow rate. In the 8052 it is determined either by the Timer 1 overflow rate, or the Timer 2 overflow rate, or both (one for transmit and the other for receive).

Figure 18 shows a simplified functional diagram of the serial port in Mode 1, and associated timings for transmit receive.

270252-15

Figure 17. Serial Port Mode 0

Figure 18. Serial Port Mode 1. TCLK, RCLK and Timer 2 are Present in the 8052/8032 Only.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "write to SBUF" signal also loads a 1 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission actually commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. (Thus, the bit

times are synchronized to the divide-by-16 counter, not to the "write to SBUF" signal).

The transmission begins with activation of SEND, which puts the start bit at TXD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TXD. The first shift pulse occurs one bit time after that.

As data bits shift out to the right, zeroes are clocked in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain zeroes. This condition flags the TX Control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 10th divide-by-16 rollover after "write to SBUF."

Reception is initiated by a detected 1-to-0 transition at RXD. For this purpose RXD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFH is written into the input shift register. Resetting the divide-by-16 counter aligns its rollovers with the boundaries of the incoming bit times.

The 16 states of the counter divide each bit time into 16ths. At the 7th, 8th, and 9th counter states of each bit time, the bit detector samples the value of RXD. The value accepted is the value that was seen in at least 2 of the 3 samples. This is done for noise rejection. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. This is to provide rejection of false start bits. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the leftmost position in the shift register, (which in mode 1 is a 9-bit register), it flags the RX Control block to do one last shift, load SBUF and RB8, and set RI. The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated.

- 1) RI = 0, and
- 2) Either SM2 = 0, or the received stop bit = 1

If either of these two conditions is not met, the received frame is irretrievably lost. If both conditions are met, the stop bit goes into RB8, the 8 data bits go into SBUF, and RI is activated. At this time, whether the above conditions are met or not, the unit goes back to looking for a 1-to-0 transition in RXD.

## More About Modes 2 and 3

Eleven bits are transmitted (through TXD), or received (through RXD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On trans-

mit, the 9th data bit (TB8) can be assigned the value of 0 or 1. On receive, the 9th data bit goes into RB8 in SCON. The baud rate is programmable to either  $\frac{1}{64}$  or  $\frac{1}{4}$  the oscillator frequency in Mode 2. Mode 3 may have a variable baud rate generated from either Timer 1 or 2 depending on the state of TCLK and RCLK.

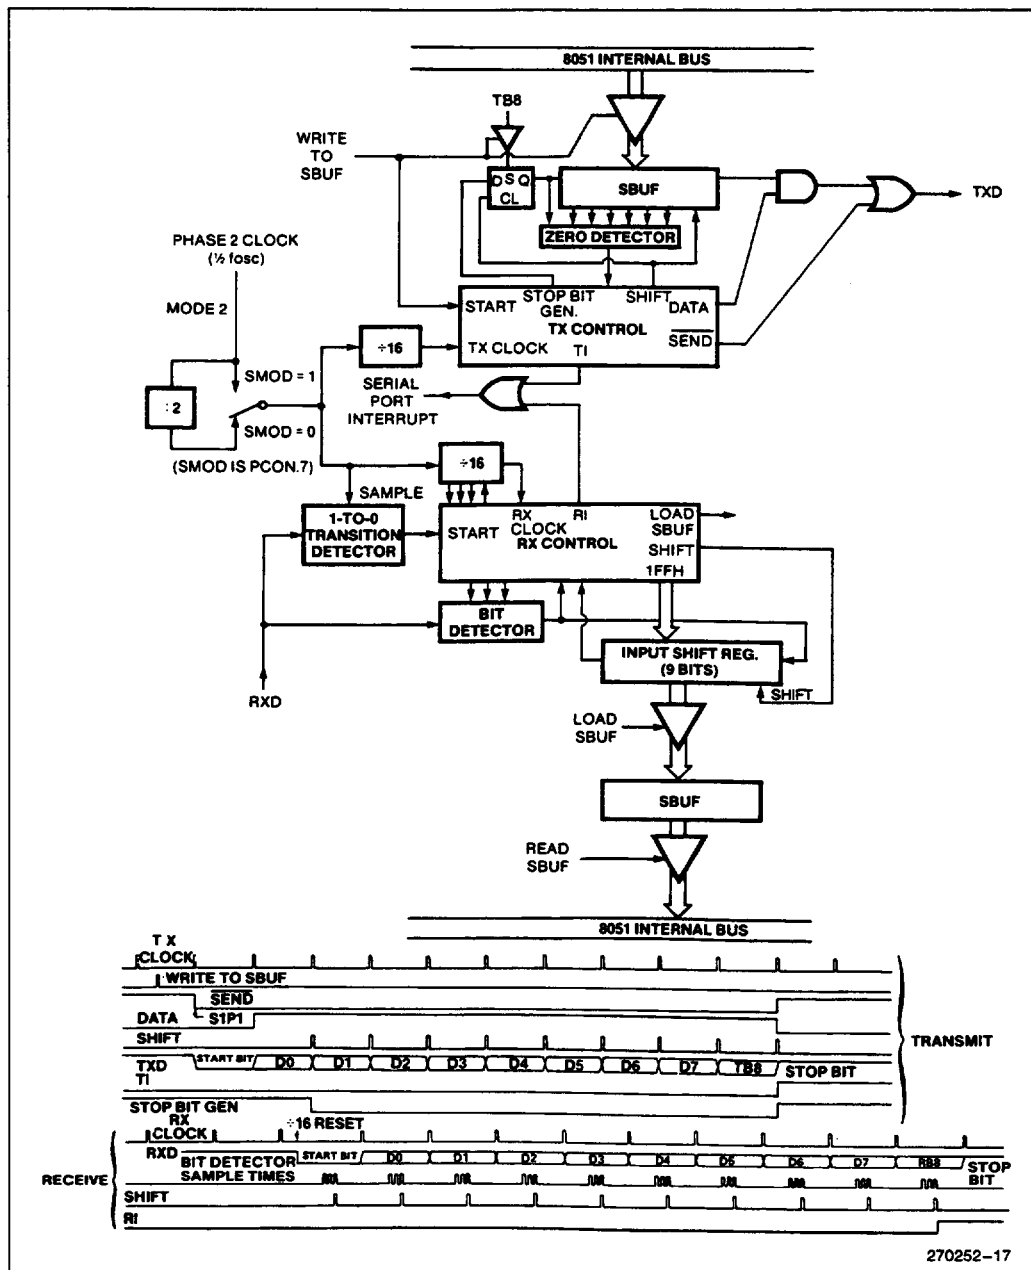

Figures 19 and 20 show a functional diagram of the serial port in Modes 2 and 3. The receive portion is exactly the same as in Mode 1. The transmit portion differs from Mode 1 only in the 9th bit of the transmit shift register.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "write to SBUF" signal also loads TB8 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. (Thus, the bit times are synchronized to the divide-by-16 counter, not to the "write to SBUF" signal.)

The transmission begins with activation of SEND, which puts the start bit at TXD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TXD. The first shift pulse occurs one bit time after that. The first shift clocks a 1 (the stop bit) into the 9th bit position of the shift register. Thereafter, only zeroes are clocked in. Thus, as data bits shift out to the right, zeroes are clocked in from the left. When TB8 is at the output position of the shift register, then the stop bit is just to the left of TB8, and all positions to the left of that contain zeroes. This condition flags the TX Control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 11th divide-by-16 rollover after "write to SBUF."

Reception is initiated by a detected 1-to-0 transition at RXD. For this purpose RXD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFH is written to the input shift register.

At the 7th, 8th and 9th counter states of each bit time, the bit detector samples the value of RXD. The value accepted is the value that was seen in at least 2 of the 3 samples. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

270252-17

Figure 19. Serial Port Mode 2

Figure 20. Serial Port Mode 3. TCLK, RCLK, and Timer 2 are Present in the 8052/8032 Only.

As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the leftmost position in the shift register (which in Modes 2 and 3 is a 9-bit register), it flags the RX Control block to do one last shift, load SBUF and RB8, and set RI. The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated:

- 1) RI = 0, and
- 2) Either SM2 = 0 or the received 9th data bit = 1

If either of these conditions is not met, the received frame is irretrievably lost, and RI is not set. If both conditions are met, the received 9th data bit goes into RB8, and the first 8 data bits go into SBUF. One bit time later, whether the above conditions were met or not, the unit goes back to looking for a 1-to-0 transition at the RXD input.

Note that the value of the received stop bit is irrelevant to SBUF, RB8, or RI.

## INTERRUPTS

The 8051 provides 5 interrupt sources. The 8052 provides 6. These are shown in Figure 21.

The External Interrupts  $\overline{INT0}$  and  $\overline{INT1}$  can each be either level-activated or transition-activated, depending on bits IT0 and IT1 in Register TCON. The flags that actually generate these interrupts are bits IE0 and IE1 in TCON. When an external interrupt is generated, the flag that generated it is cleared by the hardware when the service routine is vectored to only if the interrupt

was transition-activated. If the interrupt was level-activated, then the external requesting source is what controls the request flag, rather than the on-chip hardware.

The Timer 0 and Timer 1 Interrupts are generated by TF0 and TF1, which are set by a rollover in their respective Timer/Counter registers (except see Timer 0 in Mode 3). When a timer interrupt is generated, the flag that generated it is cleared by the on-chip hardware when the service routine is vectored to.

The Serial Port Interrupt is generated by the logical OR of RI and TI. Neither of these flags is cleared by hardware when the service routine is vectored to. In fact, the service routine will normally have to determine whether it was RI or TI that generated the interrupt, and the bit will have to be cleared in software.

In the 8052, the Timer 2 Interrupt is generated by the logical OR of TF2 and EXF2. Neither of these flags is cleared by hardware when the service routine is vectored to. In fact, the service routine may have to determine whether it was TF2 or EXF2 that generated the interrupt, and the bit will have to be cleared in software.

All of the bits that generate interrupts can be set or cleared by software, with the same result as though it had been set or cleared by hardware. That is, interrupts can be generated or pending interrupts can be canceled in software.

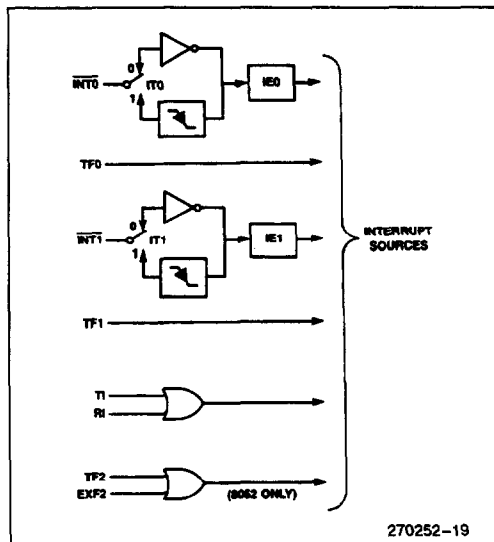

Figure 21. MCS<sup>®</sup>-51 Interrupt Sources

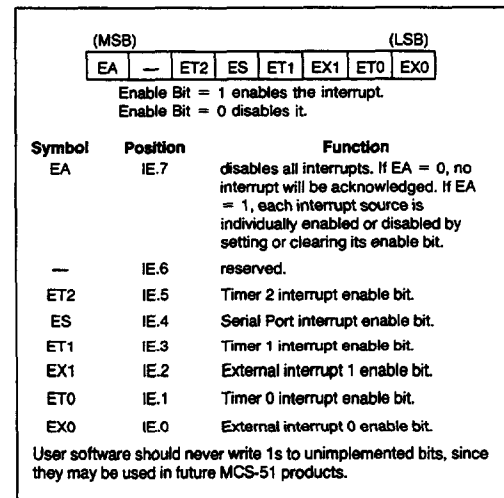

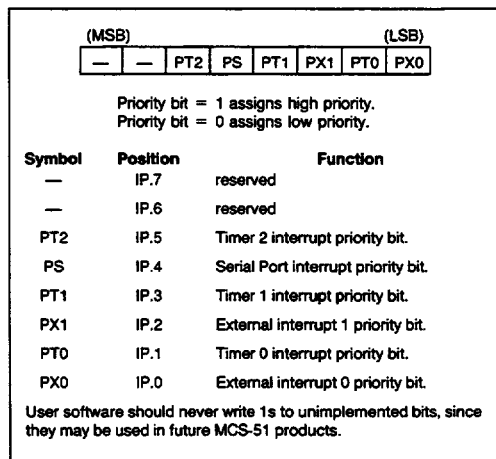

Figure 22. IE: Interrupt Enable Register

Each of these interrupt sources can be individually enabled or disabled by setting or clearing a bit in Special Function Register IE (Figure 22). IE contains also a global disable bit, EA, which disables all interrupts at once.

Note in Figure 22 that bit position IE.6 is unimplemented. In the 8051s, bit position IE.5 is also unimplemented. User software should not write 1s to these bit positions, since they may be used in future MCS-51 products.

## Priority Level Structure

Each interrupt source can also be individually programmed to one of two priority levels by setting or clearing a bit in Special Function Register IP (Figure 23). A low-priority interrupt can itself be interrupted by a high-priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

**Figure 23. IP: Interrupt Priority Register**

If two requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If requests of the same priority level are re-

ceived simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence, as follows:

Source	Priority Within Level
1. IE0	(highest)
2. TF0	
3. IE1	
4. TF1	
5. RI + TI	
6. TF2 + EXF2	(lowest)

Note that the "priority within level" structure is only used to resolve *simultaneous requests of the same priority level*.

The IP register contains a number of unimplemented bits. IP.7 and IP.6 are vacant in the 8052s, and in the 8051s these and IP.5 are vacant. User software should not write 1s to these bit positions, since they may be used in future MCS-51 products.

## How Interrupts Are Handled

The interrupt flags are sampled at S5P2 of every machine cycle. The samples are polled during the following machine cycle. The 8052's Timer 2 interrupt cycle is different, as described in the Response Time Section. If one of the flags was in a set condition at S5P2 of the preceding cycle, the polling cycle will find it and the interrupt system will generate an LCALL to the appropriate service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

1. An interrupt of equal or higher priority level is already in progress.
2. The current (polling) cycle is not the final cycle in the execution of the instruction in progress.
3. The instruction in progress is RETI or any write to the IE or IP registers.

Any of these three conditions will block the generation of the LCALL to the interrupt service routine. Condition 2 ensures that the instruction in progress will be

**Figure 24. Interrupt Response Timing Diagram**

completed before vectoring to any service routine. Condition 3 ensures that if the instruction in progress is RETI or any access to IE or IP, then at least *one more* instruction will be executed before any interrupt is vectored to.

The polling cycle is repeated with each machine cycle, and the values polled are the values that were present at S5P2 of the previous machine cycle. Note then that if an interrupt flag is active but not being responded to for one of the above conditions, and is not *still* active when the blocking condition is removed, the denied interrupt will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle is new.

The polling cycle/LCALL sequence is illustrated in Figure 24.

Note that if an interrupt of higher priority level goes active prior to S5P2 of the machine cycle labeled C3 in Figure 24, then in accordance with the above rules it will be vectored to during C5 and C6, without any instruction of the lower priority routine having been executed.

Thus the processor acknowledges an interrupt request by executing a hardware-generated LCALL to the appropriate servicing routine. In some cases it also clears the flag that generated the interrupt, and in other cases it doesn't. It never clears the Serial Port or Timer 2 flags. This has to be done in the user's software. It clears an external interrupt flag (IE0 or IE1) only if it was transition-activated. The hardware-generated LCALL pushes the contents of the Program Counter onto the stack (but it does not save the PSW) and reloads the PC with an address that depends on the source of the interrupt being vectored to, as shown below.

Source	Vector Address
IE0	0003H
TF0	000BH
IE1	0013H
TF1	001BH
RI + TI	0023H
TF2 + EXF2	002BH

Execution proceeds from that location until the RETI instruction is encountered. The RETI instruction informs the processor that this interrupt routine is no longer in progress, then pops the top two bytes from the stack and reloads the Program Counter. Execution of the interrupted program continues from where it left off.

Note that a simple RET instruction would also have returned execution to the interrupted program, but it would have left the interrupt control system thinking an interrupt was still in progress.

## External Interrupts

The external sources can be programmed to be level-activated or transition-activated by setting or clearing bit IT1 or IT0 in Register TCON. If ITx = 0, external interrupt x is triggered by a detected low at the INTx pin. If ITx = 1, external interrupt x is edge-triggered. In this mode if successive samples of the INTx pin show a high in one cycle and a low in the next cycle, interrupt request flag IEx in TCON is set. Flag bit IEx then requests the interrupt.

Since the external interrupt pins are sampled once each machine cycle, an input high or low should hold for at least 12 oscillator periods to ensure sampling. If the external interrupt is transition-activated, the external source has to hold the request pin high for at least one machine cycle, and then hold it low for at least one machine cycle to ensure that the transition is seen so that interrupt request flag IEx will be set. IEx will be automatically cleared by the CPU when the service routine is called.

If the external interrupt is level-activated, the external source has to hold the request active until the requested interrupt is actually generated. Then it has to deactivate the request before the interrupt service routine is completed, or else another interrupt will be generated.

## Response Time

The INT0 and INT1 levels are inverted and latched into the interrupt flags IE0 and IE1 at S5P2 of every machine cycle. Similarly, the Timer 2 flag EXF2 and the Serial Port flags RI and TI are set at S5P2. The values are not actually polled by the circuitry until the next machine cycle.

The Timer 0 and Timer 1 flags, TF0 and TF1, are set at S5P2 of the cycle in which the timers overflow. The values are then polled by the circuitry in the next cycle. However, the Timer 2 flag TF2 is set at S2P2 and is polled in the same cycle in which the timer overflows.

If a request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The call itself takes two cycles. Thus, a minimum of three complete machine cycles elapse between activation of an external interrupt request and the beginning of execution of the first instruction of the service routine. Figure 24 shows interrupt response timings.

A longer response time would result if the request is blocked by one of the 3 previously listed conditions. If an interrupt of equal or higher priority level is already in progress, the additional wait time obviously depends on the nature of the other interrupt's service routine. If the instruction in progress is not in its final cycle, the additional wait time cannot be more than 3 cycles, since the longest instructions (MUL and DIV) are only 4

cycles long, and if the instruction in progress is RETI or an access to IE or IP, the additional wait time cannot be more than 5 cycles (a maximum of one more cycle to complete the instruction in progress, plus 4 cycles to complete the next instruction if the instruction is MUL or DIV).

Thus, in a single-interrupt system, the response time is always more than 3 cycles and less than 9 cycles.

## SINGLE-STEP OPERATION

The 8051 interrupt structure allows single-step execution with very little software overhead. As previously noted, an interrupt request will not be responded to while an interrupt of equal priority level is still in progress, nor will it be responded to after RETI until at least one other instruction has been executed. Thus, once an interrupt routine has been entered, it cannot be re-entered until at least one instruction of the interrupted program is executed. One way to use this feature for single-step operation is to program one of the external interrupts (say,  $\overline{\text{INT0}}$ ) to be level-activated. The service routine for the interrupt will terminate with the following code:

```
JNB P3.2,$ ;Wait Here Till  $\overline{\text{INT0}}$  Goes High
JB P3.2,$ ;Now Wait Here Till it Goes Low
RETI ;Go Back and Execute One Instruction
```

Now if the  $\overline{\text{INT0}}$  pin, which is also the P3.2 pin, is held normally low, the CPU will go right into the External Interrupt 0 routine and stay there until  $\overline{\text{INT0}}$  is pulsed (from low to high to low). Then it will execute RETI, go back to the task program, execute one instruction, and immediately re-enter the External Interrupt 0 routine to await the next pulsing of P3.2. One step of the task program is executed each time P3.2 is pulsed.

## RESET

The reset input is the RST pin, which is the input to a Schmitt Trigger.

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. The CPU responds by generating an internal reset, with the timing shown in Figure 25.

The external reset signal is asynchronous to the internal clock. The RST pin is sampled during State 5 Phase 2 of every machine cycle. The port pins will maintain their current activities for 19 oscillator periods after a logic 1 has been sampled at the RST pin; that is, for 19 to 31 oscillator periods after the external reset signal has been applied to the RST pin.

While the RST pin is high, ALE and PSEN are weakly pulled high. After RST is pulled low, it will take 1 to 2 machine cycles for ALE and PSEN to start clocking. For this reason, other devices can not be synchronized to the internal timings of the 8051.

Driving the ALE and  $\overline{\text{PSEN}}$  pins to 0 while reset is active could cause the device to go into an indeterminate state.

The internal reset algorithm writes 0s to all the SFRs except the port latches, the Stack Pointer, and SBUF. The port latches are initialized to FFH, the Stack Pointer to 07H, and SBUF is indeterminate. Table 3 lists the SFRs and their reset values.

The internal RAM is not affected by reset. On power up the RAM content is indeterminate.

Figure 25. Reset Timing

**Table 3. Reset Values of the SFRs**

SFR Name	Reset Value
PC	0000H

PCON (HMOS)	0XXXXXXXB
PCON (CHMOS)	0XXX0000B

**Figure 26. Power on Reset Circuit**

## POWER-ON RESET

For HMOS devices when  $V_{CC}$  is turned on an automatic reset can be obtained by connecting the RST pin to  $V_{CC}$  through a 10  $\mu$ F capacitor and to  $V_{SS}$  through an 8.2 K $\Omega$  resistor (Figure 26). The CHMOS devices do not require this resistor although its presence does no harm. In fact, for CHMOS devices the external resistor can be removed because they have an internal pulldown on the RST pin. The capacitor value could then be reduced to 1  $\mu$ F.

When power is turned on, the circuit holds the RST pin high for an amount of time that depends on the capacitor value and the rate at which it charges. To ensure a valid reset the RST pin must be held high long enough to allow the oscillator to start up plus two machine cycles.

On power up,  $V_{CC}$  should rise within approximately ten milliseconds. The oscillator start-up time will depend on the oscillator frequency. For a 10 MHz crystal, the start-up time is typically 1 ms. For a 1 MHz crystal, the start-up time is typically 10 ms.

With the given circuit, reducing  $V_{CC}$  quickly to 0 causes the RST pin voltage to momentarily fall below 0V. However, this voltage is internally limited and will not harm the device.

### NOTE:

The port pins will be in a random state until the oscillator has started and the internal reset algorithm has written 1s to them.

Powering up the device without a valid reset could cause the CPU to start executing instructions from an indeterminate location. This is because the SFRs, specifically the Program Counter, may not get properly initialized.

## POWER-SAVING MODES OF OPERATION

For applications where power consumption is critical the CHMOS version provides power reduced modes of operation as a standard feature. The power down mode in HMOS devices is no longer a standard feature and is being phased out.

### CHMOS Power Reduction Modes

CHMOS versions have two power-reducing modes, Idle and Power Down. The input through which back-up power is supplied during these operations is  $V_{CC}$ . Figure 27 shows the internal circuitry which implements these features. In the Idle mode ( $IDL = 1$ ), the oscillator continues to run and the Interrupt, Serial Port, and Timer blocks continue to be clocked, but the

clock signal is gated off to the CPU. In Power Down (PD = 1), the oscillator is frozen. The Idle and Power Down modes are activated by setting bits in Special Function Register PCON. The address of this register is 87H. Figure 26 details its contents.

In the HMOS devices the PCON register only contains SMOD. The other four bits are implemented only in the CHMOS devices. User software should never write 1s to unimplemented bits, since they may be used in future MCS-51 products.

## IDLE MODE

An instruction that sets PCON.0 causes that to be the last instruction executed before going into the Idle mode. In the Idle mode, the internal clock signal is gated off to the CPU, but not to the Interrupt, Timer, and Serial Port functions. The CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator, and all other registers maintain their data during Idle. The port pins hold the logical states they had at the time Idle was activated. ALE and PSEN hold at logic high levels.

There are two ways to terminate the Idle. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, terminating the Idle mode. The interrupt will be serviced, and following RETI the next instruction to be executed will be the one following the instruction that put the device into Idle.

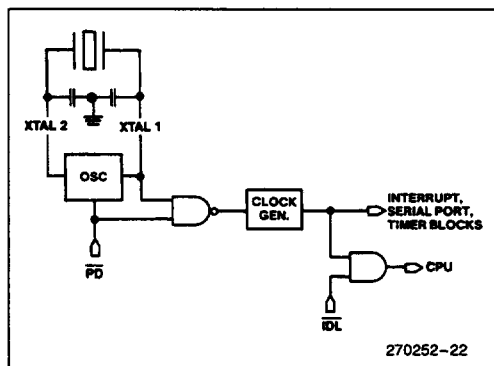

Figure 27. Idle and Power Down Hardware

(MSB)				(LSB)			
SMOD	-	-	-	GF1	GF0	PD	IDL
Symbol	Position	Name and Function					
SMOD	PCON.7	Double Baud rate bit. When set to a 1 and Timer 1 is used to generate baud rate, and the Serial Port is used in modes 1, 2, or 3.					
—	PCON.6	(Reserved)					
—	PCON.5	(Reserved)					
—	PCON.4	(Reserved)					
GF1	PCON.3	General-purpose flag bit.					
GF0	PCON.2	General-purpose flag bit.					
PD	PCON.1	Power Down bit. Setting this bit activates power down operation.					
IDL	PCON.0	Idle mode bit. Setting this bit activates idle mode operation.					

If 1s are written to PD and IDL at the same time, PD takes precedence. The reset value of PCON is (0XXX0000).  
In the HMOS devices the PCON register only contains SMOD. The other four bits are implemented only in the CHMOS devices. User software should never write 1s to unimplemented bits, since they may be used in future MCS-51 products.

Figure 28. PCON: Power Control Register

The flag bits GF0 and GF1 can be used to give an indication if an interrupt occurred during normal operation or during an Idle. For example, an instruction that activates Idle can also set one or both flag bits. When Idle is terminated by an interrupt, the interrupt service routine can examine the flag bits.

The other way of terminating the Idle mode is with a hardware reset. Since the clock oscillator is still running, the hardware reset needs to be held active for only two machine cycles (24 oscillator periods) to complete the reset.

The signal at the RST pin clears the IDL bit directly and asynchronously. At this time the CPU resumes program execution from where it left off; that is, at the instruction following the one that invoked the Idle Mode. As shown in Figure 25, two or three machine cycles of program execution may take place before the internal reset algorithm takes control. On-chip hardware inhibits access to the internal RAM during this time, but access to the port pins is not inhibited. To eliminate the possibility of unexpected outputs at the port pins, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external Data RAM.

## POWER DOWN MODE

An instruction that sets PCON.1 causes that to be the last instruction executed before going into the Power Down mode. In the Power Down mode, the on-chip oscillator is stopped. With the clock frozen, all func-

Table 4. EPROM Versions of the 8051 and 8052

Device Name	EPROM Version	EPROM Bytes	Ckt Type	VPP	Time Required to Program Entire Array
8051AH	8751H/8751BH	4K	HMOS	21.0V/12.75V	4 minutes
80C51BH	87C51	4K	CHMOS	12.75V	13 seconds
8052AH	8752BH	8K	HMOS	12.75V	26 seconds

tions are stopped, but the on-chip RAM and Special Function Registers are held. The port pins output the values held by their respective SFRs. ALE and PSEN output lows.

The only exit from Power Down for the 80C51 is a hardware reset. Reset redefines all the SFRs, but does not change the on-chip RAM.

In the Power Down mode of operation, VCC can be reduced to as low as 2V. Care must be taken, however, to ensure that VCC is not reduced before the Power Down mode is invoked, and that VCC is restored to its normal operating level, before the Power Down mode is terminated. The reset that terminates Power Down also frees the oscillator. The reset should not be activated before VCC is restored to its normal operating level, and must be held active long enough to allow the oscillator to restart and stabilize (normally less than 10 msec).

## EPROM VERSIONS

The EPROM versions of these devices are listed in Table 4. The 8751H programs at VPP = 21V using one 50 msec PROG pulse per byte programmed. This results in a total programming time (4K bytes) of approximately 4 minutes.

The 8751BH, 8752BH and 87C51 use the faster "Quick-Pulse" programming™ algorithm. These devices program at VPP = 12.75V using a series of twenty-five 100 µs PROG pulses per byte programmed. This results in a total programming time of approximately 26 seconds for the 8752BH (8 Kbytes) and 13 seconds for the 87C51 (4 Kbytes).

Detailed procedures for programming and verifying each device are given in the data sheets.

## Exposure to Light

It is good practice to cover the EPROM window with an opaque label when the device is in operation. This is not so much to protect the EPROM array from inadvertent erasure, but to protect the RAM and other on-chip logic. Allowing light to impinge on the silicon die while the device is operating can cause logical malfunction.

## Program Memory Locks

In some microcontroller applications it is desirable that the Program Memory be secure from software piracy. Intel has responded to this need by implementing a Program Memory locking scheme in some of the MCS-51 devices. While it is impossible for anyone to guarantee absolute security against all levels of technological sophistication, the Program Memory locks in the MCS-51 devices will present a substantial barrier against illegal readout of protected software.

### One Lock Bit Scheme on 8751H

The 8751H contains a lock bit which, once programmed, denies electrical access by any external means to the on-chip Program Memory. The effect of this lock bit is that while it is programmed the internal Program Memory can not be read out, the device can not be further programmed, and it *can not execute external Program Memory*. Erasing the EPROM array deactivates the lock bit and restores the device's full functionality. It can then be re-programmed.

The procedure for programming the lock bit is detailed in the 8751H data sheet.

### Two Program Memory Lock Schemes

The 8751BH, 8752BH and 87C51 contain two Program Memory locking schemes: Encrypted Verify and Lock Bits.

**Encryption Array:** Within the EPROM is an array of encryption bytes that are initially unprogrammed (all 1's). The user can program the array to encrypt the code bytes during EPROM verification. The verification procedure sequentially XNORs each code byte with one of the key bytes. When the last key byte in the array is reached, the verify routine starts over with the first byte of the array for the next code byte. If the key bytes are unprogrammed, the XNOR process leaves the code byte unchanged. With the key bytes programmed, the code bytes are encrypted and can be read correctly only if the key bytes are known in their proper order. Table 6 lists the number of encryption bytes available on the various products.

When using the encryption array, one important factor should be considered. If a code byte has the value

OFFH, verifying the byte will produce the encryption byte value. If a large block of code is left unprogrammed, a verification routine will display the encryption array contents. For this reason all unused code bytes should be programmed with some value other than OFFH, and not all of them the same value. This will ensure maximum program protection.

**Program Lock Bits:** Also included in the Program Lock scheme are Lock Bits which can be enabled to provide varying degrees of protection. Table 5 lists the Lock Bits and their corresponding effect on the microcontroller. Refer to Table 6 for the Lock Bits available on the various products.

Erasing the EPROM also erases the Encryption Array and the Lock Bits, returning the part to full functionality.

Table 5. Program Lock Bits and their Features

Program Lock Bits				Protection Type
	LB1	LB2	LB3	
1	U	U	U	No program lock features enabled. (Code verify will still be encrypted by the encryption array if programmed.)
2	P	U	U	MOVC instructions executed from external program memory are disabled from fetching code bytes from internal memory, EA is sampled and latched on reset, and further programming of the EPROM is disabled.
3	P	P	U	Same as 2, also verify is disabled.
4	P	P	P	Same as 3, also external execution is disabled.

P-Programmed  
U-Unprogrammed

Any other combination of the Lock Bits is not defined.

Table 6. Program Protection

Device	Lock Bits	Encrypt Array
8751BH	LB1, LB2	32 Bytes
8752BH	LB1, LB2	32 Bytes
87C51	LB1, LB2, LB3	64 Bytes

When Lock Bit 1 is programmed, the logic level at the  $\overline{EA}$  pin is sampled and latched during reset. If the device is powered up without a reset, the latch initializes to a random value, and holds that value until reset is activated. It is necessary that the latched value of  $\overline{EA}$  be in agreement with the current logic level at that pin in order for the device to function properly.

## ROM PROTECTION

The 8051AHP and 80C51BHP are ROM Protected versions of the 8051AH and 80C51BH, respectively. To incorporate this Protection Feature, program verification has been disabled and external memory accesses have been limited to 4K. Refer to the data sheets on these parts for more information.

## ONCETM Mode

The ONCE ("on-circuit emulation") mode facilitates testing and debugging of systems using the device without the device having to be removed from the circuit. The ONCE mode is invoked by:

1. Pull ALE low while the device is in reset and  $\overline{PSEN}$  is high;
2. Hold ALE low as RST is deactivated.

While the device is in ONCE mode, the Port 0 pins go into a float state, and the other port pins and ALE and  $\overline{PSEN}$  are weakly pulled high. The oscillator circuit remains active. While the device is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored after a normal reset is applied.

## THE ON-CHIP OSCILLATORS

### HMOS Versions

The on-chip oscillator circuitry for the HMOS (HMOS-I and HMOS-II) members of the MCS-51 family is a single stage linear inverter (Figure 29), intended for use as a crystal-controlled, positive reactance oscillator (Figure 30). In this application the crystal is operated in its fundamental response mode as an inductive reactance in parallel resonance with capacitance external to the crystal.

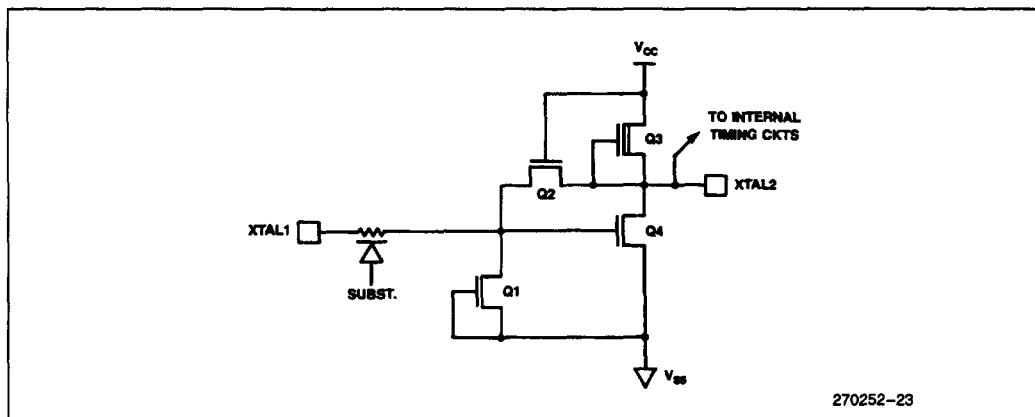

Figure 29. On-Chip Oscillator Circuitry in the HMOS Versions of the MCS®-51 Family

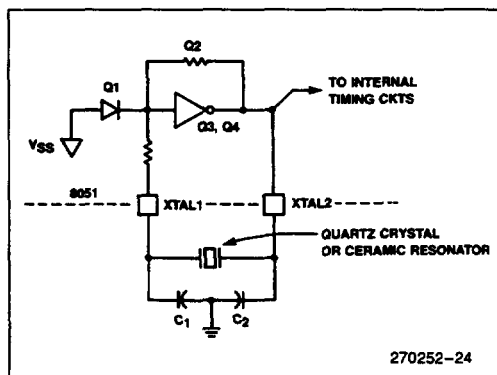

Figure 30. Using the HMOS On-Chip Oscillator

The crystal specifications and capacitance values ( $C_1$  and  $C_2$  in Figure 30) are not critical. 30 pF can be used in these positions at any frequency with good quality crystals. A ceramic resonator can be used in place of the crystal in cost-sensitive applications. When a ceramic resonator is used,  $C_1$  and  $C_2$  are normally selected to be of somewhat higher values, typically, 47 pF. The manufacturer of the ceramic resonator should be consulted for recommendations on the values of these capacitors.

In general, crystals used with these devices typically have the following specifications:

ESR (Equivalent Series Resistance)	see Figure 31
$C_O$ (Shunt Capacitance)	7.0 pF max.
$C_L$ (Load Capacitance)	30 pF $\pm$ 3 pF
Drive Level	1 mW

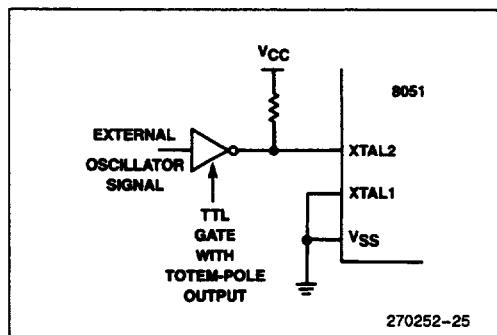

Figure 31. ESR vs Frequency

Frequency, tolerance and temperature range are determined by the system requirements.

A more in-depth discussion of crystal specifications, ceramic resonators, and the selection of values for C1 and C2 can be found in Application Note AP-155, "Oscillators for Microcontrollers," which is included in the *Embedded Applications Handbook*.

To drive the HMOS parts with an external clock source, apply the external clock signal to XTAL2, and ground XTAL1, as shown in Figure 32. A pullup resistor may be used (to increase noise margin), but is optional if VOH of the driving gate exceeds the VIH MIN specification of XTAL2.

**Figure 32. Driving the HMOS MCS®-51 Parts with an External Clock Source**

## CHMOS Versions

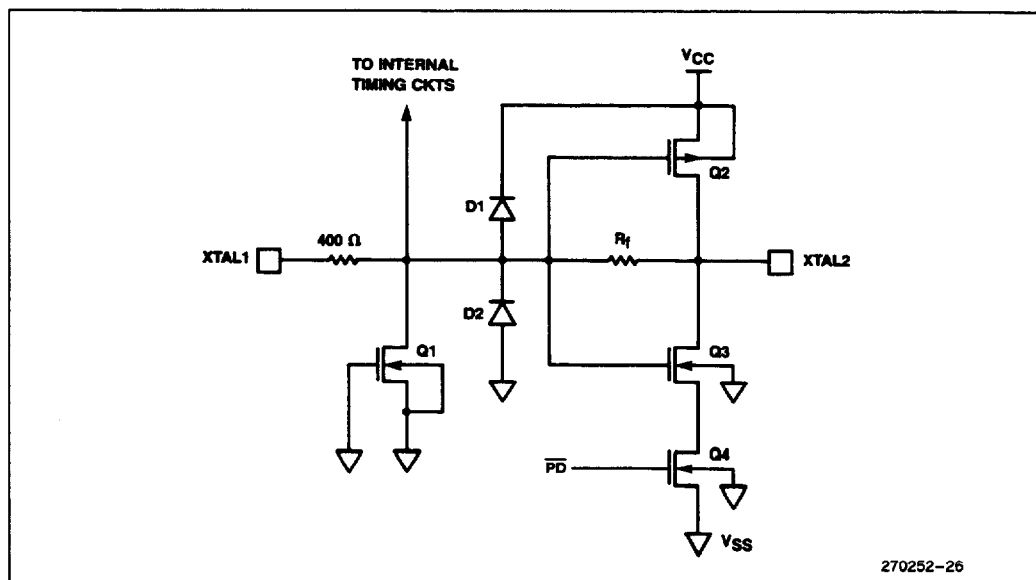

The on-chip oscillator circuitry for the 80C51BH, shown in Figure 33, consists of a single stage linear inverter intended for use as a crystal-controlled, positive reactance oscillator in the same manner as the HMOS parts. However, there are some important differences.

One difference is that the 80C51BH is able to turn off its oscillator under software control (by writing a 1 to the PD bit in PCON). Another difference is that in the 80C51BH the internal clocking circuitry is driven by the signal at XTAL1, whereas in the HMOS versions it is by the signal at XTAL2.

The feedback resistor  $R_f$  in Figure 33 consists of paralleled n- and p- channel FETs controlled by the PD bit, such that  $R_f$  is opened when PD = 1. The diodes D1 and D2, which act as clamps to VCC and VSS, are parasitic to the  $R_f$  FETs.

The oscillator can be used with the same external components as the HMOS versions, as shown in Figure 34. Typically,  $C1 = C2 = 30$  pF when the feedback element is a quartz crystal, and  $C1 = C2 = 47$  pF when a ceramic resonator is used.

To drive the CHMOS parts with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 float, as shown in Figure 35.

**Figure 33. On-Chip Oscillator Circuitry in the CHMOS Versions of the MCS®-51 Family**

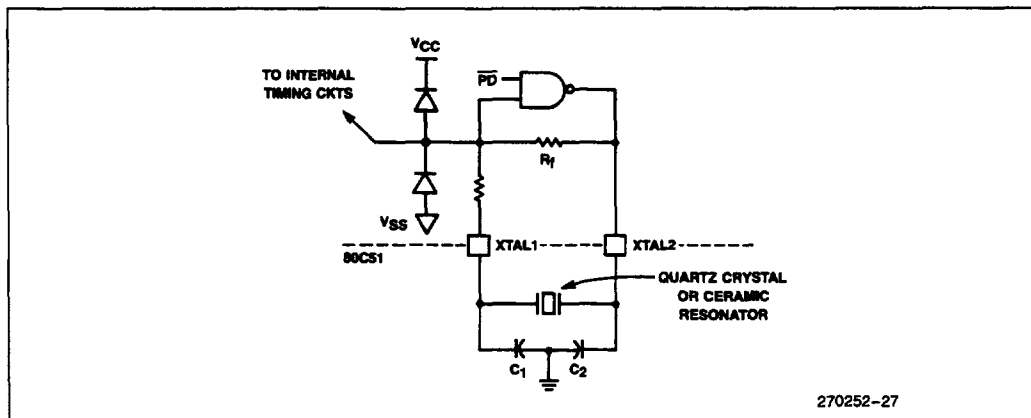

Figure 34. Using the CHMOS On-Chip Oscillator

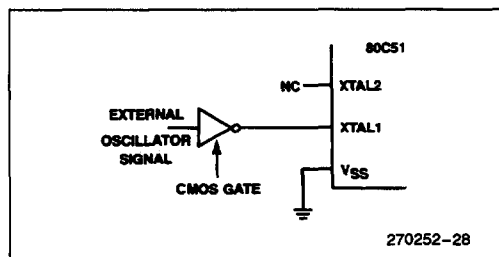

Figure 35. Driving the CHMOS MCS®-51 Parts with an External Clock Source

The reason for this change from the way the HMOS part is driven can be seen by comparing Figures 29 and 33. In the HMOS devices the internal timing circuits are driven by the signal at XTAL2. In the CHMOS devices the internal timing circuits are driven by the signal at XTAL1.

## INTERNAL TIMING

Figures 36 through 39 show when the various strobe and port signals are clocked internally. The figures do not show rise and fall times of the signals, nor do they show propagation delays between the XTAL signal and events at other pins.

Rise and fall times are dependent on the external loading that each pin must drive. They are often taken to be something in the neighborhood of 10 nsec, measured between 0.8V and 2.0V.

Propagation delays are different for different pins. For a given pin they vary with pin loading, temperature, VCC, and manufacturing lot. If the XTAL waveform is taken as the timing reference, prop delays may vary from 25 to 125 nsec.

The AC Timings section of the data sheets do not reference any timing to the XTAL waveform. Rather, they relate the critical edges of control and input signals to each other. The timings published in the data sheets include the effects of propagation delays under the specified test conditions.
